Short running title: Identification of poorly known molossids from Central Amazonia.

Words: 5182

1
2
3
4 **Abstract**
5

6 *Eumops maurus* and *E. hansae* are rarely captured Neotropical molossid bats for which
7 information on taxonomy, natural history, and spatial distribution are scarce. This translates into
8 a poor understanding of their ecology and limits the delimitation of useful characters for their
9 identification. Here, we describe records of these two molossids from the Central Brazilian
10 Amazon, providing data on their external and craniodental morphology, DNA barcode (COI)
11 sequences complemented by acoustic data for the species. Morphological characters, DNA
12 sequence data and phylogenetic relationships within the genus *Eumops* were consistent with
13 those previously described for both species. Echolocation call characteristics did not differ
14 significantly so as to be useful for separating *E. maurus* and *E. hansae* from other congeners.
15 Our records are, respectively the first and the second for Central Amazonia as one individual
16 previously attributed to *E. amazonicus* from Manaus may be considered a junior synonym for *E.*
17 *hansae*. These new records increase the extent of the species' known ranges, partially filling in
18 previous existing gaps in their distribution in central South America. Our data further suggest
19 that these molossid bats forage in a wider range of habitats than previously thought.

4 **Introduction**
5

6 The Molossidae are a diverse family of aerial insectivorous bats, with more than 100 extant
7 species whose center of richness is in tropical and subtropical regions (Gregorin et al. 2016;
8 Simmons 2005). Due to their high-flying habits of foraging above forest canopies and over open
9 landscapes, molossids are usually hard to capture using ground level mist-nets, as a consequence
10 of which knowledge of their ecology and distribution is still limited (Barataud et al. 2013;
11 Gregorin, et al. 2016; Jung et al. 2014). Moreover, the relatively few records of molossids often
12 come from colonies found within urban areas, leading to the biased perception that these bats
13 may particularly be associated with anthropic environments (López-Baucells et al. 2017a; Sodr 
14 et al. 2008). Overall, data on molossid species from South America are scarce and despite the
15 fact that multidisciplinary research on these bats is globally increasing (Gager et al. 2016) their
16 natural history remains largely unknown, particularly for some of the more elusive species.

31
32

33
34 Bonneted bats of the genus *Eumops* Miller, 1906 are widely distributed throughout the New
35 World, ranging from the southeastern United States to Patagonia, including some Antillean
36 islands (Gardner 2008). *Eumops* is one of the most diverse molossid genera with 17 species
37 currently recognized (Gregorin, et al. 2016). However, knowledge about the distributions of
38 *Eumops* species is limited (Medina et al. 2012). Moreover, the taxonomy of the genus is in flux,
39 as recently several previously unrecognized species have been described and the phylogeny of
40 *Eumops* has been revised (Bartlett et al. 2013; Gregorin 2009; Gregorin, et al. 2016; Medina et
41 al. 2014).

53
54 Both Sanborn's Bonneted Bat, *Eumops hansae* Sanborn, 1932, and the Guianan Bonneted Bat *E.*
55 *maurus* (Thomas, 1901) are widely distributed throughout the Neotropics, but rarely captured.
56 Their occurrence has been documented only through a handful of records across their
57
58
59
60
61
62
63
64
65

1
2
3
4 distributonal ranges. While *E. hansae* has been recorded in 12 countries across Central and
5
6 South America, *E. maurus* is only known from eight localities from Guiana, Brazil, Venezuela,
7
8 Peru and Ecuador (Fig. 1). Not only are the ranges of these two species still poorly documented,
9
10 but also basic natural history, ecological and genetic data are scarce and their echolocation calls
11
12 remain undescribed (Best et al. 2001a, b). Here, we present data on the morphology,
13
14 echolocation, and mitochondrial DNA of *E. hansae* and *E. maurus* from the Central Brazilian
15
16 Amazon. We discuss the potential of each kind of information to aid in the reliable identification
17
18
19
20
21 of the two species.

Material and Methods

Study area

Field work was carried out at the Biological Dynamics of Forest Fragmentation Project (BDFFP), located ca. 80 km north of Manaus in the Central Amazon, Brazil (2°25'S, 59°50'W; elevation 30-125 m a.s.l.) (Lovejoy and Bierregaard 1990). The predominant vegetation in this region is lowland primary *terra firme* forest (Bruna and Kress 2002), with minor areas of secondary forest (8,325ha). Mean annual temperature is 26 °C (de Oliveira and Mori 1999) and annual rainfall ranges from 1,900-3,500 mm, with a rainy season from October to May. The primary forest canopy is 30-37 m tall, with emergent trees up to 55 m (Laurance et al. 2017).

[Figure 1 near here]

Bat sampling

Extensive standardized mist-netting was carried out across the BDFFP landscape between 2011 and 2014 as part of a comprehensive project on the effects of forest fragmentation on phyllostomid bats (Farneda et al. 2015; Rocha et al. 2017). Additionally, during the same period mist nets (12x2.5 m, 16 mm mesh, ECOTONE, Sopot, Poland) were also set opportunistically across streams and small lakes, both during the rainy and the dry season. Nets were left open for six hours after sunset and checked every 20-30 minutes. This opportunistic sampling resulted in captures of three adult males of *E. maurus* and three adult females of *E. hansae* over natural lakes, one in the Km 41 reserve (2°26'51.69"S, 59°45'2.05"W) and one in Colosso reserve (2°24'39.34"S, 59°52'8.55"W), between April and June 2014. All bats were captured in different nights. Lakes measured approximately 100x112 and 80x55 m respectively, and were up to 2 m deep. Both lakes underwent seasonal water level fluctuations, but carried water throughout the

1
2
3
4 year. However, they greatly differed regarding human use. The lake in Colosso was used as a
5
6 water reservoir for cattle and horses, whereas the one in Km 41 is located far away from human
7
8 settlements and surrounded by primary forest.
9

10
11 One individual per species was collected as voucher specimen. From all individuals, including
12
13 the ones that were released, standard external measurements were taken in the field (see below).
14
15 We also took wing tissue samples using commercial wing biopsy punches (2 mm, Stiefel
16
17 Laboratories, Inc., Germany). Voucher specimens were deposited at the Mammal Collections of
18
19 the Instituto Nacional de Pesquisas da Amazônia (INPA 6731 *Eumops maurus*; INPA 6732
20
21 *Eumops hansae*) in accordance with Brazilian conservation and animal welfare laws. Research
22
23 was carried out under scientific license from the Instituto Chico Mendes de Conservação da
24
25 Biodiversidade—ICMBio (permit number 26877-2).
26
27
28
29
30
31

32 33 *Morphology*

34
35 External and craniodental characters measured are based on Eger (1977) and Freeman (1981),
36
37 and were recorded in millimeters (mm) using digital calipers accurate to 0.1 mm (Fig. 2). Body
38
39 mass was recorded in grams (g) with a Pesola spring scale (accuracy of 0.5g). Measurements are
40
41 defined as follows: total length (TL); tail (TAIL); thumb length (ThL); nail (Na); calcar length
42
43 (Cal); antitragus width (AntW); antitragus height (AntH); hind foot length (HF); ear length (E);
44
45 forearm length (FA); tibia length (TiL); fourth metacarpal length (MET-IV); first phalanx of the
46
47 fourth digit (PHA1-IV); greatest length of the skull (GLS); condyloincisive length (CIL);
48
49 zygomatic breadth (ZB); postorbital breadth (PB); braincase breadth (BB); maxillary toothrow
50
51 length (MTRL); breadth across molars (BAM); breadth across canines (BAC); mandibular
52
53 toothrow length (MANDL) and mandibular length (MANDLT).

[Figure 2 near here]

Echolocation recordings

Echolocation call recordings were obtained from captured individuals (two individuals per species were recorded) using a Pettersson D1000X detector (Pettersson Elektronik AB, Uppsala, Sweden) after each individual's release in forest clearings. To minimize bias in acoustic parameters, only those sequences recorded at least 5 seconds after the release (when the bats were normally flying at higher altitudes) were considered for analysis. Individual *Eumops hansae* were easily released from the hand as their small size allows them to take off even in quite cluttered environments from relatively low heights (they are more maneuverable than other molossid species), despite their narrow wings. With *Eumops maurus* the release process was slightly more complicated and we tried to facilitate their take-off by placing the bats high up on the trunks of dead trees or on poles. The detector was placed 15 m away from the animals. Recordings were made at a sampling frequency of 250 kHz, with 16 bits/sample. For sound analysis, we used a customized 512 point fast Fourier transform (FFT) with a Hanning window for both spectrograms and power spectrum. To characterize the echolocation calls, the following parameters were measured from 24 pulses for *E. hansae* and 49 pulses for *E. maurus*, using Kaleidoscope v.3.1.4b (Wildlife Acoustics, USA): peak frequency or frequency with maximum energy (FME), start frequency (St-freq) and end frequency (End-freq) (Jung, et al. 2014; López-Baucells et al. 2016a). Other common measurements such as bandwidth and pulse duration were not considered as they are particularly prone to be biased after hand release. To minimize measurement error and bias, we only measured those pulses from the recorded echolocation call sequences whose intensity was around 20 dB higher than the background noise.

1
2
3
4 *DNA barcoding and phylogenetic analyses*
5
6

7 DNA of the two *Eumops* species was extracted from muscle tissue of the collected individuals.
8
9 For preserved tissue samples, PCR amplifications of COI were carried out in 15 µL reactions
10 containing 60 ng of DNA, 1.5 U of Platinum Taq (Invitrogen®, Carlsbad, CA, USA), 1 x
11 Platinum Taq PCR buffer, 1.5 mM MgCl₂, 200 µM dNTPs set (Invitrogen®) and 0.3 µM of each
12 primer. The primers used for amplifications were modified from Folmer et al. (1994), available
13 from the BOLD project (Ratnasingham & Hebert, 2007). We used the following cycling scheme
14 for PCRs: 2 min at 94°C followed by 35 cycles of 30 s at 94°C, 40 s at 50°C for primer
15 annealing and 1 min at 72°C for extension, and a final 10 min extension at 72°C after the last
16 cycle. Sequencing of both strands was carried out on an ABI 3130 (Applied Biosystems®)
17 automated sequencer using Big Dye Terminator Cycle Sequencing methodology (Applied
18 Biosystems®). The sequences produced in this study were deposited in the BOLD database
19 (<http://www.boldsystems.org>) under the process ID BRMAM620-15.

37 We retrieved sequence data available for six species of *Eumops* and also for *Tadarida*
38 *brasiliensis* (outgroup) from BOLD and GenBank to perform phylogenetic analyses for the
39 genus, and to infer the position of our specimens in the phylogeny. GenBank accession numbers
40 are given in Table S1. We used MEGA 6 (Tamura et al. 2013) to align and edit the sequences,
41 and to calculate genetic distances based on a Kimura 2-parameter (K2P) model (Kimura 1980).

4 **Results**
5

6
7 *Morphology*
8
9

10 We identified *Eumops hansae* based on a combination of characters, including its (i) small size
11 (FA = 38.7 mm, Table 1), (ii) ears connected by a membranous stripe on the forehead, (iii)
12 square-shaped tragus, and (iv) blackish brown dorsal pelage contrasting with the paler venter
13 with three-colored banded fur. Our female specimen had a long skull with large and well-defined
14 basisphenoid pits (Fig. 2D–F), and the third commissure of M3 nearly as well developed as the
15 second (Fig. 2E). Individuals of *E. maurus* (all males) were readily identified based on external
16 measurements (Table 2), the species' distinctive band of pure white hairs in the proximal ventral
17 plagiopatagium (measuring approximately 5x20 mm), and the narrow band along the lateral
18 body. The skull of our specimen had paired oval, and relatively shallow pits in its basisphenoid
19 bone, and small anterior upper premolars (Fig. 2).

37

38 *Echolocation calls*
39
40

41 Echolocation calls of both *E. maurus* and *E. hansae* consisted of a quasi-constant frequency
42 (QCF) component, and were almost constant at very low frequencies (Table 3, Fig. 3). As usual
43 for molossids, the fundamental was the harmonic with the maximum energy in both cases. For *E.*
44 *maurus*, peak frequency averaged 25.3 kHz, ranging between 19-30 kHz. *Eumops hansae*
45 emitted low-frequency QCF pulses at a peak frequency of 21.9 kHz (range 18-24 kHz). For both
46 species, the shape of the pulses was clearly concave and downward modulated, being the first
47 part of the pulse highly modulated, and the terminal part almost constant. Based on our
48 recordings there was no evidence of pulse alternation in either species.

6

7 *DNA barcoding and phylogenetic analyses*
8
9

10 Average pairwise COI distances between *Eumops* species ranged from 3.2% (*E. auripendulus*
11 versus *E. maurus*) to 17.4% (*E. hansae* versus *E. perotis*) (Table 4 & 5), and intraspecific genetic
12 distances ranged from 0% (*E. maurus* and *E. floridanus*) to 0.9% (*E. hansae*). Sequence
13 similarity between the individuals of *E. hansae* from Guiana and our specimen from Brazil was
14 high (99.3 - 99.8%). In contrast, similarity between our Brazilian specimen and the sequence
15 from a single individual from Belize was considerably lower (96.3%). For *E. maurus*, the single
16 published barcoding sequence comes from Guiana (Clare et al. 2011), and fully (100%) matched
17 the sequence obtained for our Brazilian specimen.
18
19

20 Our specimen of *E. hansae* formed a clade with a specimen from Guiana, nested within a clade
21 composed of representatives from Belize and several other individuals from Guiana, sister to all
22 other *Eumops* species included in this analysis. The samples of *E. maurus* from Ecuador and
23 Brazil formed a well-supported sister clade to *E. auripendulus* (Fig. 4).

Discussion

We used multiple methodological approaches in combination (external and craniodental morphology, DNA barcode and acoustic data) to confirm new occurrence records for 2 poorly known molossid species. Despite the clear advantages and improvements that multidisciplinary studies provide to scientists, they are still fairly rare within the literature, especially on tropical bat species (but see Gager, et al. 2016). Such integrative studies should be widely encouraged, as they can advance the further description and understanding of the diversity of bat species across the continent more efficiently than single-method studies.

Species distribution

Taxonomic uncertainties of *E. hansae* have led to knowledge on its natural history and current distribution lagging considerably behind that for other Neotropical molossids (Bartlett, et al. 2013). Although being one of the least known *Eumops* species, *E. hansae* had previously been captured in a wide range of habitats. These include forests off coastal areas (Álvarez-Castañeda and Álvarez 1991; Koopman 1982), tropical rainforests (Eisenberg 1989; Lee and Bradley 1992; Paglia et al. 2012; Simmons and Voss 1998), savannas (Ibáñez and Ochoa 1989), premontane humid forests (Ochoa et al. 1988), dry forests (Pineda et al. 2008), and tropical lowland forest in hilly terrains (Graham and Barkley 1984). However, despite the broad range of habitats where it has been found, captures were almost always over ponds, large clearings, rivers and large lagoons. The presence of this species in such a diverse range of environments suggests that *E. hansae* is not restricted to a particular habitat, and could in fact be widespread (Fig. 1). *Eumops maurus* inhabits a diverse array of habitats, including savannas, although it is often associated with swamps dominated by the palm *Mauritia flexuosa*, gallery forests, swampy evergreen forest

1
2
3
4 and urban spaces (Best, et al. 2001b; Sodr , et al. 2008). Overall, specimens from only seven
5
6 localities are known for this poorly known bat (Fig. 1) comprising a total of six females and a
7
8 single male from Guiana, the holotype. Our records from Manaus (3 males) fill a gap in the
9
10 center of the previously known distribution (Fig. 1) representing a westward range expansion of
11
12 1900 km from Corumb  (Brazil) and 620 km southward from the Kanaku mountains (French
13
14 Guiana: Sodr , et al. (2008)). Of the three individuals, one voucher was collected, which
15
16 represents the second male specimen available in collections.
17
18
19
20

21 *Morphology*

22
23
24 Morphological variation within molossids makes reliable species identification sometimes
25
26 difficult and may lead to inconsistent results among studies (Gregorin 2009), particularly if based
27
28 mostly on continuous characters. That is, for instance, the case for the use of forearm length to
29
30 separate *E. maurus* from other *Eumops* species. In these cases, sometimes consistent discrete
31
32 characters, such as the presence of the large lateral stripe of white ventral fur alongside its body,
33
34 and the oval shaped, relatively shallow pit in its basisphenoid bone (Best, et al. 2001b; Gregorin
35
36 2009), make *E. maurus* easy to identify. As reported previously for specimens from Surinam,
37
38 there was a small anterior upper premolar present in our voucher, which Eger (1977) reported to
39
40 be absent in the holotype, and therefore this character may be considered a variable condition for
41
42 the species. Our specimen of *E. maurus* has a somewhat smaller forearm compared to the range
43
44 of forearm lengths of specimens from other localities, including the holotype (male) collected in
45
46 Guiana (Table 2). Cranial measurements of our specimen did not differ much from those of the
47
48 holotype. Unfortunately, no additional *E. maurus* male skull measurements are available for
49
50 comparison. Based on the sparse cranial measurements available for male and female *E. maurus*
51
52 we tentatively posit that males have somewhat longer skulls than females, but are otherwise
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 similar in size. All measurements from *E. hansae* fell within the expected range for the species,
5
6 and the few measurements available for males were larger than those for females (Table 1).
7
8

9 *Echolocation calls*

10
11 In contrast to other families, most molossid species are known to forage in open spaces adapting
12
13 their echolocation to long-range prey detection. Like their congeners, quasi-constant frequency
14
15 pulses characterize the echolocation calls of *E. maurus* and *E. hansae* and reflect their adaptation
16
17 to flying in open spaces (Aldridge and Rautenbach 1987; Russo and Jones 2002). There is a
18
19 considerable overlap in peak frequency between *E. maurus* and other *Eumops* species, including
20
21 *E. hansae*, *E. auripendulus*, *E. glaucinus*, and *E. dabbenei* (Table 3, Fig. 3) thus rendering this
22
23 parameter useless for species identification. Some Neotropical molossids such as *Molossus*
24
25 *molossus*, *M. rufus* and *Promops centralis* can be easily identified acoustically based on the
26
27 alternation of pulses, call shape (concave vs convex or upward- versus downward-modulated for
28
29 instance), and peak frequencies (Barataud, et al. 2013; Jung, et al. 2014; López-Baucells, et al.
30
31 2016a). Unfortunately, based on our recordings, no parameter was found to be diagnostic so as to
32
33 allow reliable discrimination between either of the two *Eumops* species. Until more acoustic data
34
35 become available, allowing for a comprehensive genus-wide analysis, we recommend grouping
36
37 all species from the genus *Eumops* into a single phonic group. The fact that we could not find
38
39 any pulse alternation could result from the stress caused by the handling and the proximity of
40
41 cluttered forest where they were released. More calls recorded under natural conditions would be
42
43 essential to complement the description of the echolocation call characteristics of the species.
44
45 The fact that other poorly studied species of *Eumops* have similar calls stresses the need for
46
47 further studies to evaluate additional criteria for their acoustic discrimination.

1
2
3
4 *DNA barcoding and phylogenetic analyses*
5
6

7
8 Cytochrome c Oxidase subunit I (COI) has been proposed as a global scale barcode for animal
9
10 species identification (Kress et al. 2015; Ratnasingham and Hebert 2007) and has already been
11
12 successfully used to aid in the identification and discovery of Neotropical bats (Clare et al. 2013;
13
14 Lim and Arcila Hernandez 2015). Our sequences from *E. hansae* and *E. maurus* were properly
15
16 classified at species level using the DNA barcode database. This corroborates, as suggested by
17
18 Clare, et al. (2011), that DNA barcoding is a powerful auxiliary tool to identify specimens. While
19
20 COI sequences available in GenBank are still scarce for *E. maurus*, for *E. hansae* several
21
22 sequences can be found. Nevertheless, for both of these *Eumops* species and congeners there are
23
24 large sampling gaps throughout their distribution range. The position of *E. hansae* within the
25
26 *Eumops* tree has shifted historically to either basal to all species of *Eumops*, or nested with small
27
28 *Eumops* (Bartlett, et al. 2013; Gregorin, et al. 2016). Our phylogenetic analyses recovered *E.*
29
30 *hansae* as sister to all other *Eumops*, as did the concatenated data of Bartlett, et al. (2013) and
31
32 Gregorin, et al. (2016). Alternatively, *E. hansae* has been previously hypothesized to be sister to
33
34 all small-sized *Eumops* (*bonariensis*, *patagonicus*, *nanus*) based on molecular (Medina, et al.
35
36 2014) and morphological evidence (including *delticus*) (Gregorin 2009, Medina, et al. 2014). On
37
38 the other hand, the position of *E. maurus* within *Eumops* seems more stable as this taxon is
39
40 frequently recovered as the sister of *auripendulus* based both on molecular (Bartlett, et al. 2013;
41
42 Gregorin, et al. 2016; Medina, et al. 2014) and morphological data (Gregorin 2009).
43
44

45
46 DNA barcoding is still not always employed in studies that report new species occurrences or
47
48 distribution range expansions in many taxa (Bezerra et al. 2005; Khedkar et al. 2016; López-
49
50 Baucells et al. 2013, 2014; Moras et al. 2015; Tavares et al. 2014; but see Khedkar, et al. 2016;
51
52 López-Baucells et al. 2016b, 2017b; Nagy, et al. 2012; Seyhan and Turan 2016). Its increasingly

4 **Acknowledgments**
5

6 We would like to thank Oriol Massana, Diogo Ferreira, Marta Acácio, Fabio Farneda, Gilberto
7
8 Fernández and Madalena Boto for fieldwork assistance and José Luis Camargo, Rosely Hipólito,
9
10 and Ary Jorge Ferreira for logistic support. We thank INPA for providing the research permits to
11
12 capture and collect bat specimens within the study area. This work was financially supported by
13
14 the Portuguese Foundation for Science and Technology under project grant
15
16 PTDC/BIABIC/111184/2009 (CFJM), and scholarships SFRH/BD/80488/2011 (RR) and
17
18 PD/BD/52597/2014 (ALB). VCT is supported by a PNPD/CAPES fellowship program. This is
19
20 publication XXX in the Technical Series of the BDFPP. This research has been carried out under
21
22 ICMBio permit (26877-2). Finally, we thank two anonymous reviewers for their constructive
23
24 comments on an earlier version of the manuscript.

Table 3: Search flight call parameters for *Eumops maurus*, *E. hansae* and other *Eumops* species. Mean \pm SE, observed range (in parentheses).

Species	Source	N (n)*	Call type	Call shape	FME	Start frequency	End frequency
<i>E. maurus</i>	Current study	49 (2)	mono	QCFd	25.29 \pm 2.613 (19.2 - 30.8)	33.45 \pm 2.86 (25.6 - 39.1)	19.80 \pm 2.72 (14.3 - 24.3)
<i>E. hansae</i>	Current study	24 (2)	mono	QCFd	21.86 \pm 1.79 (17.9 - 23.9)	34.77 \pm 3.83 (25.6 - 40.1)	13.78 \pm 1.96 (11 - 16.8)
<i>E. auripendulus</i>	Personal recordings	6	low	QCFd	23.13 \pm 1.76 (16.4 - 27.5)	34.35 \pm 3.13 (23.8 - 42.2)	19.97 \pm 2.63 (12 - 26.7)
	Barataud (2013)	2	low	QCFd	26.70 (26.3 - 27)		
	Jung et al. (2014)	41 (9)	low	FMu/QCFd		32.4 \pm 4.3	18.2 \pm 1.6
	Barataud (2013)	16	middle	FMd/QCF	23.30 (20.1 - 25.7)		
	Current study	6	high	QCFd	25.77 \pm 2.01 (23.1 - 28.7)	28.59 \pm 2.32 (25.9 - 33.7)	24.73 \pm 2.20 (21.2 - 27.7)
<i>E. dabbeni</i>	Barataud (2013)	22	high	QCF	18.70 (17.3 - 21.8)		
	Jung (2014)	27 (9)	high	FMu/QCFd		35.8 \pm 4.1	21.9 \pm 1.6
	Jung et al. (2014)	22 (6)	low	FMu/QCFd		21.3 \pm 1.2	13.7 \pm 0.5
<i>E. glaucinus</i>	Jung et al. (2014)	23 (6)	high	FMu/QCFd		24.6 \pm 2.3	15.8 \pm 0.8
	Jung et al. (2014)	37 (10)	low	FMu/QCFd		27.4 \pm 3.4	19 \pm 0.4
<i>E. nanus</i>	Jung et al. (2014)	16 (10)	high	FMu/QCFd		29.3 \pm 4.2	20.3 \pm 0.3
	Jung et al. (2014)	8 (4)	low	FM/QCFd		27.9 \pm 0.1	25.2 \pm 0.2
<i>E. underwoodi</i>	Jung et al. (2014)	9 (4)	high	FM/QCFd		30.5 \pm 2.5	26.8 \pm 0.8
	Miller (2003)	1046 (150)	mono	QCFd	16.25 \pm 4.2 (12.43 - 20.75)	15.4 \pm 2.88 (12.43 - 18.18)	18.09 \pm 2.7 (15.76 - 21.05)

* N (n) = number of pulses (number of individuals); Call type: mono = no frequency alternation; low/middle/high = echolocation that alternates frequency on subsequent pulses; Call shape: QCF = Quasi Constant Frequency; FM = Frequency Modulated; u = upward-modulated; d = downward-modulated; FME: Frequency of maximum energy.

Table 4: Average pairwise Kimura 2-parameter percentage sequence divergence among *Eumops* species based on 657 base pairs of the COI gene for 26 individuals. Intraspecific divergence is on the diagonal.

	n	<i>E. auripendulus</i>	<i>E. floridanus</i>	<i>E. hansae</i>	<i>E. maurus</i>	<i>E. perotis</i>	<i>E. underwoodi</i>
<i>E. auripendulus</i>	8	0.3					
<i>E. floridanus</i>	2	12.4	0.0				
<i>E. hansae</i>	12	16.3	13.4	0.9			
<i>E. maurus</i>	2	3.2	12.9	16.5	0.0		
<i>E. perotis</i>	1	12.1	10.0	17.4	11.8	-	
<i>E. underwoodi</i>	1	14.0	10.4	17.1	13.2	10.3	-

Table 5. List of taxa used in the present study and BOLD and GenBank accession numbers.

Species	Accession numbers (GenBank)
<i>Eumops auripendulus</i>	EF080345 - EF080349; JF448843; JF454657; KR608253
<i>Eumops hansae</i>	EF080350 - EF080357; JF435947; JF44884, BOLDAAC7539
<i>Eumops maurus</i>	JF448845; BOLDAAY3575
<i>Eumops perotis</i>	KP4219
<i>Eumops underwoodi</i>	KP734223
<i>Eumops floridanus</i>	KR337728, KR337729
<i>Tadarida brasiliensis</i>	JF446884

Figures

1
2 Fig. 1 Distribution of *Eumops maurus* and *E. hansae* in South America. [1] Pompeya Sur, Napo
3 Province, Ecuador (Reid et al., 2000); [2] Uverito, State of Monagas, Venezuela (Sánchez et al.,
4 1992); [3] Kanaku mountains, Guiana (holotype) (Thomas, 1901); [4] Peixe/Angical Hydroelectric
5 Plant, State of Tocantins (Sodré et al., 2008); [5] Corumbá Hydroelectric Plant IV, State of Goiás
6 (Sodré et al., 2008); [6] São Paulo, State of São Paulo (Sodré et al., 2008); [7] Santuario Nacional
7 Pampas, Peru (Luna et al., 2002); [8] San Juan: Asociación de Viviendas 15 de Mayo, Peru (Diaz et
8 al., 2011); [9] Chiapas, Mexico (Álvarez and Álvarez-Castañeda, 1990); [10] Lancetilla Atlantida,
9 Honduras (Lee and Bradley, 1992) [11] Several locations, Costa Rica (Eger, 1977; Gardner, 2008;
10 Hall, 1981); [12] Peru (Graham and Barkley, 1984); [13] Venezuela (Eisenberg, 1989); [14]
11 Venezuela (Handley, 1976); [15] French Guiana (Simmons and Voss, 1998); [16] Manaus, State of
12 Amazonas (Handley, 1955); [17] Bolivia (Ibáñez and Ochoa, 1989); [18] Uberlândia, Minas Gerais
13 (Stutz et al., 2004); [19] São Paulo (Novais unpublished); [20] Colônia Hansa, Joinville, Santa
14 Catarina (holotype) (Sanborn 1932). According to Eger (1977), in Suriname and Brazil there are
15 two *E. hansae* with imprecise location. Map downloaded and adapted from the map of National
16 Aggregates of Geospatial Data Collection (NAGDC): *Population, Landscape and Climate*
17 *Estimates, v3: Biomes South America*; from the NASA Socioeconomic Data and Applications
18 Center (SEDAC) at <http://sedac.ciesin.columbia.edu/data/collection/groads/maps/gallery/search>.
19 Accessed on 20/08/2015.

20
21
22 Fig 2. *Eumops maurus* (INPA 6731; male). – A. Dorsal view. – B. Ventral view. – C. Lateral view.
23 *E. hansae* (INPA 6732; female). – D. Dorsal view. – E. Ventral view. – F. Lateral view. Note the
24 large and well-defined basisphenoid pits and the third commissure of M3 developed in *E. hansae*
25 (E). Scale bar: 5mm.

26
27
28 Fig. 3 Echolocation calls of *Eumops maurus* (A: spectrogram of single pulse; B power spectrum; C
29 commuting flight sequence) and *E. hansae* (D: spectrogram of single pulse; E power spectrum; F
30 commuting flight sequence).

31
32
33 Fig. 4 Tree resulting from the Bayesian analysis of COI showing the evolutionary relationships
34 among *Eumops* species. Values above branches represent Bayesian posterior probabilities (BPP)
35 and below branches, the maximum likelihood (ML) bootstrap. Our specimens are represented by
36 asterisks. Abbreviations are as follows: BEL: Belize; BRA: Brazil; ECU: Ecuador; GUA:
37 Guatemala; GUY: Guyana; PER: Peru; USA: United States of America.
