25 **ABSTRACT**

26 *Callicebus* is a Neotropical primate genus of the family Pitheciidae, which
27 currently comprises 34 recognized species. Based on their morphological traits
28 and geographic distribution, these species are currently assigned to five
29 groups: the *C. moloch*, *C. cupreus*, *C. donacophilus*, *C. torquatus*, and *C.*
30 *personatus* groups, although in the past, alternative arrangements have been
31 proposed based on the analysis of morphological data. The principal
32 disagreements among these arrangements are related to the composition of the
33 *C. moloch* group. In the present study, we tested the different taxonomic
34 proposals for the *C. moloch* group, based on the molecular analysis of nuclear
35 markers (*Alu* insertions and flanking regions) and three mitochondrial genes
36 (16S, COI and *Cyt b*), with a total of approximately 7 kb of DNA sequence
37 data. Phylogenetic reconstructions based on maximum likelihood and
38 Bayesian inference methods indicated that the species of the current *C.*
39 *cupreus* group should be reintegrated into the *C. moloch* group. In addition,
40 our results corroborated previous studies suggesting that the species of the
41 current *C. personatus* group form a distinct species group. We also observed a
42 relatively subtle level of divergence between *C. dubius* and *C. caligatus*.
43 While the known diversity of *Callicebus* is considerable, these findings
44 indicate that the relationships among groups and species may still not be
45 completely understood, highlighting the need for further research into the
46 biological, geographic and genetic variability of these primates, which will be
47 fundamental to the effective conservation of the genus.

49 **Key words:** *Callicebus moloch* group, species group, taxonomy, new species.

451 **INTRODUCTION**

52 *Callicebus* Thomas, 1903 is one of the four Neotropical primate genera of the
53 family Pitheciidae [Schneider and Sampaio 2015]. In the first taxonomic review of
54 this genus, Elliot [1913] recognized 22 monotypic species. Almost a half century
55 later, Hill [1960] published a comprehensive review of the social structure,
56 reproduction, behavior, parasitology, geographic distribution and systematics of the
57 subfamilies Callicebinae, Aotinae, Pitheciinae and Cebinae. In that work, his
58 arrangement of the genus *Callicebus* included only six species, but 34 subspecies.
59 Hershkovitz [1963] identified only two species, from the Amazon (*Callicebus*
60 *moloch*) and Orinoco (*C. torquatus*) basins, but later revised this number to 13
61 [Hershkovitz 1988; 1990]. These species were allocated to four species groups, based
62 on cranial and post-cranial morphology and pelage coloration: (i) the *Callicebus*
63 *modestus* group, with one species, which Hershkovitz [1988] identified as an “isolated
64 relict species”; (ii) the *C. donacophilus* group, with three species; (iii) the *C. moloch*
65 group with eight species, and (iv) the *C. torquatus* group, with a single species.
66 Subsequently, Kobayashi [1995] using meristic cranial characters, pelage,
67 geographical distribution and karyotypes, suggested five species groups: (i) *C.*
68 *donacophilus*; (ii) *C. moloch*; (iii) *C. cupreus*; (iv) *C. personatus* and (v) *C. torquatus*
69 (Table 1). In that study, the *C. moloch* group was divided into three species (*C.*
70 *moloch*, *C. cupreus* and *C. personatus*), while *C. modestus* was incorporated into the
71 *C. donacophilus* group.

72 van Roosmalen et al. [2002] followed the proposal of Kobayashi [1995], but
73 raised all subspecies to the species level, based on the phylogenetic species concept.
74 Since then, nine new putative species have been discovered and incorporated into

1
2
3 75 these groups based on morphological, ecological and biogeographical criteria
4
5 76 [Dalponte et al., 2014; Silva Júnior et al., 2013; Vermeer and Tello-Alvarado, 2015].
6
7

8 The genus *Callicebus* is widely distributed in tropical South America. Three of
9
10 78 the species groups (*C. torquatus*, *C. cupreus* and *C. moloch* groups) are found in the
11
12 79 Amazon and Orinoco basins [Kobayashi, 1995], the *C. donacophilus* group is found
13
14 80 primarily in the dry Chaco region, while the *C. personatus* group is centered on the
15
16 81 Brazilian Atlantic Forest biome, Cerrado and Caatinga (Fig. 1).
17

18 The composition of the *C. moloch* group has changed a number of times, from a
19
20 83 maximum of 14 taxa (species and subspecies) in Hershkovitz [1988, 1990] to six in
21
22 84 the most recent proposal [van Roosmalen et al., 2002]. The purpose of the present
23
24 85 study is to clarify the taxonomic arrangement of the *Callicebus moloch* group based
25
26 86 on molecular data obtained from both nuclear and mitochondrial regions.
27
28

29
30 87

31 32 88 **METHODS**

33 34 89 **Samples and molecular markers**

35
36 90 A total of 64 samples were obtained from blood or muscle tissue preserved in absolute
37
38 91 ethanol. These samples were obtained from the following Brazilian institutions: the
39
40 92 Goeldi Museum (MPEG), National Institute of Amazonian Research (INPA), Federal
41
42 93 University of Pará (UFPA), Federal University of Rondônia (UNIR), Federal
43
44 94 University of Amazonas (UFAM), Rio de Janeiro Primate Center (CPRJ-INEA), and
45
46 95 the National Primate Center (CENP) in Ananindeua, Pará. This research adhered to
47
48 96 the legal requirements of Brazil legislation as well as to “Principles for the Ethical
49
50 97 Treatment of Non Human Primates” of the American Society of Primatologists
51
52 98 (ASP).
53
54
55
56
57
58
59
60

1
2
3 99 For this study, putative species identifications were based on morphological and
4
5 100 pelage coloration (*sensu* van Roosmalen et al. [2002]). We included specimens of
6
7 101 species assigned to the *C. moloch* group by van Roosmalen et al's [2002]
8
9
10 102 classification, as well as those falling into van Roosmalen et al's [2002] *C. cupreus*,
11
12 103 and *C personatus* groups because some of those species were considered part of the
13
14 104 *moloch* group by others authors (e.g., Groves [2001], Hershkovitz [1988, 1990]). We
15
16 105 also included samples of individuals from newly described species *C. vieirai* and *C.*
17
18 106 *miltoni* [Gualda-Barros et al., 2012; Dalponte et al., 2014]. The sample codes, sources
19
20 107 and localities are shown in Table 2, and the localities are plotted in Fig. 1. Samples of
21
22 108 the other pitheciid genera (*Pithecia*, *Chiropotes* and *Cacajao*) were used as the
23
24 109 outgroup for the phylogenetic analyses. Our phylogenetic inferences were based on
25
26 110 ten nuclear and three mitochondrial markers (Table S1). The three mtDNA genes
27
28 111 were rRNA16S (543 bps), cytochrome oxidase subunit I – COI (605 bps) and
29
30 112 cytochrome *b* - CYT *b* (1074 bps). The nuclear regions correspond to sites including
31
32 113 mobile *Alu* elements, other repetitive sequences, and their flanking regions.
33
34
35
36
37
38
39

115 **Extraction, amplification and sequencing of DNA**

40
41 116 Total DNA was obtained with Promega's Wizard Genomic kit, according to the
42
43 117 manufacturer's protocol. The mitochondrial and nuclear regions were amplified by
44
45 118 polymerase chain reaction (PCR). For the PCRs, a final volume of 15 µl was used,
46
47 119 containing about 30 ng of genomic DNA, 2.4 µl of dNTPs (1.25mM), 1.5 µl of 10X
48
49 120 Buffer (200 mM Tris-HCl, 500 mM KCl), 1 µl of MgCl₂ (25 mM), 1 µl of each
50
51 121 primer (0.2 µM), and 1 U of Taq DNA polymerase. The amplification protocol was
52
53 122 initiated with four minutes of denaturation at 95°C, followed by 35 cycles of three
54
55 123 stages: (i) denaturation at 95°C for 30 s, (ii) annealing at a specific temperature (see
56
57
58
59
60

1
2
3 124 Table S1), and (iii) extension at 72°C for 30 seconds. After completion of the 35
4
5 125 cycles, there was a final extension stage at 72°C for seven minutes. The PCR products
6
7 126 were then purified using polyethylene glycol and ethanol [Paithankar and Prasad,
8
9 127 1991]. The sequencing reactions were run using the BigDye Terminator Sequencing
10
11 128 kit v. 3.1 (Life Technologies) and the reaction products were separated and visualized
12
13
14 129 using an ABI 3500xl automatic sequencer (Life Technologies).
15
16
17
18

19 131 **Sequence alignment, identification of Alus and phylogenetic analyses**

20
21 132 The DNA sequences were aligned initially using ClustalW [Thompson et al.,
22
23 133 1994] and then corrected manually using the BioEdit v. 7.2.5 software [Hall, 1999].
24
25 134 Saturation was assessed using DAMBE version 5.3.109 [Xia, 2013]. We used the
26
27 135 software PartitionFinder [Lanfear et al., 2012] to test different partition schemes and
28
29 136 select the most appropriate evolutionary model. We were particular concerned with
30
31 137 evaluating whether evolutionary rates differed among the three types of markers
32
33 138 (nuclear Alu elements, regions flanking Alu sites, and mitochondrial genes) (see
34
35 139 Table S2). For PartitionFinder analyses, we set the search method to “greedy”,
36
37 140 allowed unlinked branch lengths, and evaluated results based on Bayesian information
38
39 141 criterion (BIC). Our analysis suggested that the best scheme for our data set was to
40
41 142 separate it into two partitions (nuclear and mitochondrial regions). The regions
42
43 143 containing interspaced repeats (SINEs and LINEs) were identified using the software
44
45 144 RepeatMasker (<http://www.repeatmasker.org>).
46
47
48

49 145 Phylogenetic reconstruction were made using both the maximum likelihood (ML)
50
51 146 method, run in RaxML v.8 [Stamatakis, 2014] with 1000 bootstrap replicates and
52
53 147 Bayesian inference (BI) as implemented in MrBayes v. 3.2.1 [Ronquist and
54
55 148 Huelsenbeck, 2003]. In MrBayes, the analysis of substitution model parameters was
56
57
58
59
60

1
2
3 149 unlinked across partitions. Two independent runs were initiated simultaneously with
4
5 150 four independent Markov-Chain Monte Carlo (MCMC) chains (1 cold and 3 heated).
6
7 151 The MCMC algorithm was based on 500,000 cycles (generations), sampled every
8
9 152 5000 cycles, with 25% of the samples being discarded as burn-in. Convergence was
10
11 153 assessed by comparing the two runs. The MCMC output was visualized and
12
13 154 diagnosed in Tracer v. 1.6 [Rambaut et al., 2014]. The run was considered
14
15 155 satisfactory when, for all traces, the Effective Sample Size (ESS) values were over
16
17 156 200. For interspecific comparisons, matrices of genetic distances based on the K2P
18
19 157 model [Kimura, 1980] were generated for each marker in the MEGA v. 6.0 software
20
21 158 [Tamura et al., 2013]. Given the large number of specimens analyzed, genetic
22
23 159 distances were also estimated using only two specimens of each species for
24
25 160 visualization purposes.

26
27
28
29 161 We also perform a Bayesian multispecies coalescent analysis in *BEAST [Heled,
30
31 162 Drummond, 2010] with two runs of 300 million generations each. The nucleotide
32
33 163 substitution model chosen for the concatenated nuclear regions, and the mitochondrial
34
35 164 genes CytB, COI and 16S were respectively: GTR+Gamma; GTR+Gamma;
36
37 165 HKY+Gamma; GTR+Gamma. For the clock model, both strict and correlated relaxed
38
39 166 clock were tested. For species tree and population Size model, Yule and Piecewise
40
41 167 linear and constant root were the priors used, respectively. For model parameters and
42
43 168 statistics, the default priors were used.

44
45
46
47 169 The logs of these two runs were visualized in Tracer to check if the ESS values
48
49 170 were above 200. When considered adequate, the logs were combined in LogCombiner
50
51 171 v. 1.8.3 and after a 20% burn-in the trees were summarized in the TreeAnnotator v.
52
53 172 1.8.3. All trees (ML, BI, and species tree) were visualized and edited in FigTree v.
54
55 173 1.4.2 [Rambaut, 2012].

56
57
58
59 174
60

1
2
3 175 **RESULTS**

4
5 176 **Data and missing data**

6
7 177 A total of 747 sequences were generated, which correspond to 88.4% of the
8
9 178 number of possible sequences (see S3 for details). The total sequence of 7121 bps
10
11 179 included 4899 bps of nuclear markers and 2222 bps of the mitochondrial markers
12
13 180 (Table S2). Gaps in the data arose due to the lack of biological material in some
14
15 181 samples or the failure of the PCR amplification.
16
17 182

18
19
20
21 183 **Saturation, phylogenetic analysis, species tree and genetic divergences**

22
23 184 No saturation was detected in any of the markers (data not shown). The
24
25 185 Maximum Likelihood and Bayesian approaches generated well supported topologies
26
27 186 for the majority of the nodes (Fig. 2). A clear and significant division was found
28
29 187 between the species of the *C. personatus* group (Atlantic Forest) and the remaining
30
31 188 (Amazonian) species analyzed in this study. In the Amazonian group, *C. hoffmannsi*
32
33 189 appears to have diverged first, followed by a trichotomy of groups – (i) *C. cupreus*, *C.*
34
35 190 *brunneus*, *C. caligatus* and *C. dubius*, (ii) *C. cinerascens* and *C. miltoni*, and (iii) *C.*
36
37 191 *moloch*, *C. vieirai* and *C. bernhardi*.

38
39
40 192 The species tree inferred using *BEAST had the same topology as that
41
42 193 reconstructed under maximum likelihood using RAxML and Bayesian inference as
43
44 194 implemented in MrBayes, regardless of whether a constant or relaxed molecular clock
45
46 195 was applied. All currently recognized species were assigned to well-supported clades,
47
48 196 with the exception of *C. moloch*, which consistently appeared paraphyletic, with
49
50 197 individuals collected near to Alta Floresta, left bank of the Tapajós river identified as
51
52 198 *C. moloch2* forming a distinct clade, sister to other *C. moloch1* individuals and *C.*
53
54 199 *vieirai* (Fig. 3).
55
56
57
58
59
60

1
2
3 200 Pairwise genetic distances (K2P) were estimated between clades in the whole
4
5 201 dataset, as well as between species in a reduced dataset. Genetic divergence between
6
7 202 *C. bernhardi* and *C. cinerascens* varied from 4.7% to 4.9% (Table S4), which is
8
9
10 203 consistent with the genetic distances between the *C. moloch* and *C. cupreus* groups
11
12 204 recognized by Kobayashi [1995]. Based on the topology obtained in the present study,
13
14 205 five clades were identified: **(M)** *C. moloch*, *C. vieirai* and *C. bernhardi*; **(Ci)** *C.*
15
16 206 *cinerascens* and *C. miltoni*; **(Cu)** *C. cupreus*, *C. brunneus*, *C. caligatus* and *C. dubius*;
17
18 207 **(H)** *C. hoffmannsi*, and **(P)** the species of the *C. personatus* group.
19

20
21 208 We estimated genetic distances within and between these five clades for both
22
23 209 mitochondrial sequences only (COI, 16S and CYT b) and for concatenated
24
25 210 mitochondrial and nuclear sequences. Intra-clades distances were lowest for clade **H**
26
27 211 and highest for clade **P**. Inter-clade distances were, overall, much higher between
28
29 212 clade **P** and the remaining clades, while clades **M**, **Cu**, **Ci** and **H** all had similar
30
31 213 genetic distances from one another (Table 3).

215 **DISCUSSION**

216 As mentioned previously, the configuration of *Callicebus* species groups has
217 been the subject of much discussion, although there are two basic proposals for the *C.*
218 *moloch* group. One is that of Kobayashi [1995], which includes *C. moloch*, *C.*
219 *cinerascens*, *C. brunneus*, *C. hoffmannsi*, and *C. baptista*, and is similar to the
220 proposal of van Roosmalen et al. [2002]. The second proposal is that of Groves
221 [2001], which is in fact similar to that of Hershkovitz [1990]. Groves [2001] added *C.*
222 *cupreus* (and its subspecies) and *C. personatus* to the *C. moloch* group, in addition to
223 the species suggested by Kobayashi [1995] and Kobayashi and Langguth [1999].

224 The results of the present study nevertheless indicate emphatically that the *C.*
225 *personatus* clade from the Brazilian Atlantic Forest is a group quite distinct from the
226 Amazonian forms. This is supported by the greater genetic distances between the *C.*
227 *personatus* and the Amazonian clades of 6.6–7.2% for the nuclear sequences and
228 more than 13% for the mitochondrial ones (CytB = 13.0% and COI = 13.7%). A
229 similar conclusion was reached by Perelman et al. [2011] who also observed that the
230 Atlantic species are very distantly related to the Amazonian ones, estimating a
231 separation time of approximately 10 Ma. This result contrasts with Hershkovitz's
232 [1990] and Groves's [2001] hypotheses that placed the titi monkeys of the Atlantic
233 Forest inside the *C. moloch* group.

234 In the Amazonian group, the results of the present study identified a
235 monophyletic clade including *C. cupreus*, *C. brunneus*, *C. caligatus* and *C. dubius*,
236 which was supported strongly by bootstrap and Bayesian credibility values, with *C.*
237 *moloch* in a sister clade together with *C. cinerascens*, *C. miltoni*, *C. bernhardi*, and *C.*
238 *vieirai*. This is incompatible with the proposal of Kobayashi [1995] and Kobayashi
239 and Langguth [1999], which is also followed by van Roosmalen et al. [2002], which

1
2
3 240 placed *C. brunneus* more closely related *C. moloch* and *C. cinerascens* than with *C.*
4
5 241 *cupreus*.

7 242 The result of the present study indicate that the groups proposed by Kobayashi
8
9 243 [1995], Kobayashi & Languth [1999] and van Roosmalen et al. [2002] are not
10
11 244 monophyletic, and are incompatible with the genetic similarity between species of the
12
13 245 *C. cupreus* and *C. moloch* groups. Until further confirmatory research, then, we would
14
15 246 recommend adopting an arrangement similar to that proposed by Groves [2001], in
16
17 247 which the *C. moloch* group would include the following species (species in brackets
18
19 248 were not analyzed in the present study): *C. moloch*, *C. hoffmannsi*, *C. cinerascens*, *C.*
20
21 249 *brunneus*, [*C. baptista*], *C. bernhardi*, *C. vieirai*, *C. miltoni*, *C. cupreus*, *C. caligatus*,
22
23 250 *C. dubius*, [*C. discolor*], [*C. ornatus*], [*C. stephennashi*], [*C. aurepalatti*], [*C.*
24
25 251 *caquetensis*], [*C. toppini*] and [*C. urubambensis*].

27
28
29 252 Kobayashi (1995) pointed out that the morphological differences between the
30
31 253 species of the *C. moloch* and *C. cupreus* groups are extremely subtle, although their
32
33 254 parapatric geographic distribution, divided by the Madeira River, was considered to
34
35 255 be decisive to consider them as distinct taxonomic groups. The Madeira is a major
36
37 256 geographic barrier for a number of taxa, and separates two Amazonian centers of
38
39 257 endemism – the Inambari and Rondônia centers [Da Silva et al., 2005]. Even so, a
40
41 258 number of other primate taxa (*Saguinus weddelli*, *Saimiri ustus*, *Lagothrix cana* and
42
43 259 *Ateles chamek*) are found on both banks of the upper Madeira, suggesting the
44
45 260 occurrence of gene flow (active or passive) between the margins of this river.

47
48
49 261 In addition, the topology obtained in the present study indicate that the specimens
50
51 262 collected near to Alta Floresta, left bank of the Tapajós river identified as *C. moloch2*,
52
53 263 they are a distinct taxon of others *C. moloch* here studied (*C. moloch1*) and also of *C.*
54
55 264 *vieirai*. This suggests that the specimens of *C. moloch2* may represent an undescribed

1
2
3 265 species of the *C. moloch* group; even though this area is within the known geographic
4
5 266 distribution *C. moloch* or that the differences between both *C. moloch* groups (1 and
6
7 267 2) and *C. vieirai* represents the extremes of a gradient of variation within *C. moloch*,
8
9
10 268 that due to the scattered nature of the sampling in this study is impossible to evaluate.

11 269 The results of the present study also indicate that *C. hoffmannsi* is one of the most
12
13 270 basal within the *C. moloch* group, rather than *C. dubius*, as suggested by Hershkovitz
14
15 271 [1988]. As no samples of *C. baptista* were available for analysis, it was not possible to
16
17 272 evaluate its relationship with *C. hoffmannsi*, which is generally considered to be its
18
19 273 sister species. With regard to the two most recently-described species, *C. miltoni* and
20
21 274 *C. vieirai*, the results provided some important insights. While it is morphologically
22
23 275 similar to *C. bernhardi* in its pelage, for example, *C. miltoni* is closely related, in
24
25 276 genetic terms, to *C. cinerascens*. By contrast, a close genetic relationship was found
26
27 277 between *C. vieirai* and *C. moloch*, which was expected, given the occurrence of *C.*
28
29 278 *vieirai* between the Iriri and Xingu rivers, an area surrounded by the geographical
30
31 279 distribution of *C. moloch*. One other interesting finding was the close relationship
32
33 280 between *C. dubius* and *C. caligatus*, which was in fact the smallest genetic divergence
34
35 281 found between any two species. This supports the position of Groves [2001], who
36
37 282 concluded that *C. dubius* is a geographical variant of *C. caligatus*, rather than a valid
38
39 283 species.
40
41
42
43
44

45 284 We hope that these new insights into the considerable diversity of the titi
46
47 285 monkeys will contribute to the definition of the taxonomic arrangement of the genus.
48
49 286 Further research into their diversity, biogeography, and genetic variability of these
50
51 287 primates will be fundamental to a more complete understanding of their phylogeny,
52
53 288 and the effective conservation of the genus.

M= *C. moloch* clade; **Cu**= *C. cupreus* clade; **Ci**= *C. cinerascens* clade; **H**= *C. hoffmannsi* clade and **P**= *C. personatus* clade; Nuc.=Nuclear.

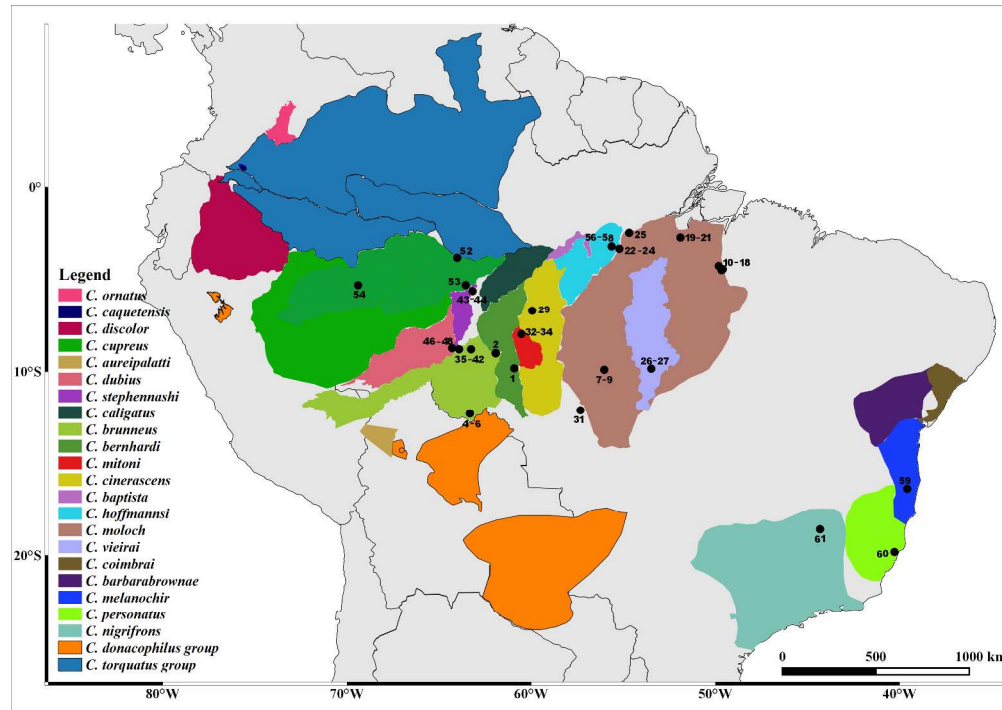

Figure 1. Geographic distribution of the genus *Callicebus* and map of South America showing the sites from which the specimens were obtained for analysis in the present study. The different colors represent each *Callicebus* species, and the site numbers correspond to those in Table 2. The hatched areas represent the ranges of four of the species groups (*C. torquatus*, *C. cupreus*, *C. donacophilus*, and *C. personatus*), while the species of the *C. moloch* group are represented by colored polygons.

296x209mm (300 x 300 DPI)

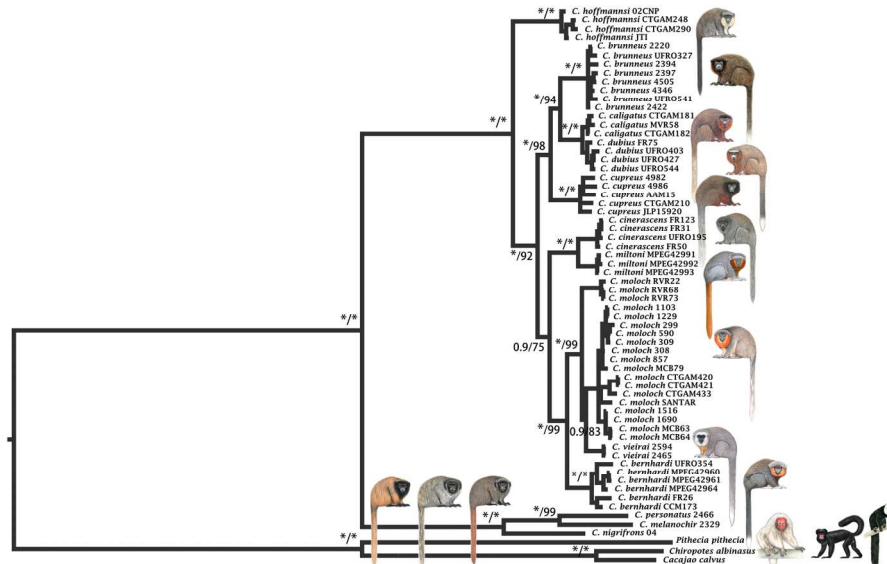

Figure 2. Phylogenetic tree based on a combined ~7 Kb sequence of nuclear and mitochondrial regions. Bootstrap support/posterior probability for the Maximum Likelihood and Bayesian inference analyses are shown at each node. Asterisks represent maximum support of values. Source *Callicebus* drawings Stephen Nash.

677x381mm (72 x 72 DPI)

Figure 3. Phylogenetic tree obtained in BEAST v. 1.8.1. (Drummond et al., 2012). Only nodes with posterior probabilities below 1 are shown (see arrows).

361x270mm (72 x 72 DPI)
