The analysis on heat transmission and fluid flow characteristics within the cavity is useful to improve the features of several applications including energy storage devices and hybrid fuel cells. With this motivation, the present model investigates the characteristics of magneto-convective heat transmission and fluid flow within a square porous enclosure with hot and cold slits. The heat transfer features of electrically conducting hybrid nanofluids $Fe_3O_4-MWCNT-$water and $Fe_3O_4-MWCNT-$kerosene is analyzed inside the enclosure. The non-Fourier thermal flux model is deployed and the internal heat absorption/generation effect is considered. The Marker-And-Cell (MAC) numerical scheme is adopted to solve the transformed dimensionless mathematical model with associated initial-boundary conditions. An exhaustive parametric investigation is implemented to estimate the influence of key parameters on the transport phenomena. The computations show that augmenting the Hartmann number values modify the fluid flow and temperature features substantially for both the hybrid nanofluids. Enhancing the values of nanoparticles volume fraction promotes the heat transfer. When 5% $Fe_3O_4-MWCNT$ nanoparticles are suspended into water and kerosene base fluids, $Fe_3O_4-MWCNT-$kerosene hybrid nanofluid achieves 6.85% higher mean heat transfer rate compared to $Fe_3O_4-MWCNT-$water hybrid nanoliquid. In the existence of heat absorption, the mean rate of heat transfer of $Fe_3O_4-MWCNT-$water hybrid nanofluid is 78.92% lower than $Fe_3O_4-MWCNT-$kerosene hybrid nanoliquid. Greater energy transmission is noticed in the case of $Fe_3O_4-MWCNT-$kerosene hybrid nanofluid and the enhanced fluid flow is noticed in the case of $Fe_3O_4-MWCNT-$water hybrid nanofluid. Fourier's model ($\delta_e = 0$) estimates higher heat transfer rate than that of the Cattaneo–Christov (non-Fourier) heat flux model ($\delta_e \neq 0$).

Keywords: Magnetized hybrid nanofluids, square cavity, Cattaneo Christov heat flux, MAC computation, heat source/sink.

I. INTRODUCTION

Mixed convection arises in a variety of thermal engineering applications wherein energy transfer occurs without the presence of any external forces. The vital engineering applications of mixed convection include in nuclear reaction systems, air-condition refrigerators, cooling of electronic devices, solar collectors, and heat exchangers. As a result, numerous researchers scrutinized the features of mixed convective flow and heat transmission inside the cavities by employing various theoretical techniques[1,2]. In the current era, due to several practical applications, natural and mixed convective flows are investigated inside different types of geometries, for example, tilted cavity, annular cavity, open cavity, square, L-shape, rectangular, triangular, and trapezoidal enclosures[3–10]. Convective flow and heat transmission in such cavities features in diverse engineering systems including room ventilation, nuclear and chemical reactors, geothermal systems, drying devices, fuel cells, fire dynamics in compartments, food processing, and thermal energy storage systems[11].

The thermophysical properties of ordinary fluids, such as thermal conductivity may be enhanced by adding nanoparticles into base fluids. In numerous practical applications, including petroleum recovery, heat pipes, chemical processes, lubrication, surface coating, heat exchangers, biomedical systems, environmental remediation, and electronic cooling systems due to their enhanced thermal efficiency[12–16]. Nanofluids are prepared by suspending the nano-sized $(1-100nm)$ particles into a base fluid. The nanoparticles are synthesized from metals $(Cu, Ag, Al, \& Au)$, metal$-$oxides $(Fe_2O_3, SiO_2, ZnO, TiO_2, Al_2O_3, CuO, CuO_2, Fe_3O_4)$, carbon-based (MWCNTs, SWCNTs, & carbon nanotubes), and metal nitride (AlN)[17–19]. These metallic/non$-$metallic nanoparticles are carefully suspended into the ethylene glycol/water/propylene glycol/kerosene/ oil or other base fluids, to augment the base fluid's thermal conductivity. It is to be noted that metallic nanoparticles like Al, Cu, Au, Ag, Fe, Zn and Ni are recognized for their excellent thermal conductivity.

Although silver and gold nanoparticles feature very high thermal conductivities, relatively sparse investigations have been conducted because of the high cost of these precious metals. Accordingly, adding the metallic oxide nanoparticles, which are less costly, may have a favorable influence on the production of more efficacious nanofluids in terms of economical optimization in addition to the stability and thermal performance[20,21]. However, preparing the nanofluids by using a single type of nanoparticles (unitary nanofluids) has shown its limitations and deficiencies. Therefore, researchers have developed the hybrid nanofluids by combining more than one type of nanoparticles with base-fluids. This concept has been revealed as an innovative approach to enhance the energy transmission in various devices, notably in fuel cells. However, it is critical to judiciously select appropriate and compatible types of nanoparticles. Many researchers have shown numerically and experimentally that hybrid nanofluids consistently produce a high heat transfer rate and greater thermal efficiency compared to ordinary fluids or unitary nanofluids[22,23]. Currently, the hybrid nanofluids are being explored in a wide spectrum of emerging technologies including heat pipes, cooling techniques in nuclear power systems, generators, transformers, thermal barrier coatings, automotive radiators, braking systems, electronic devices, and manufacturing. Further applications can be found in biomedical drug delivery, air conditioning, sensor surface finishing, etc[24,25].

Convective flow in porous media plays a major role in the design of chemical catalytic reactors, ground-water flows, fuel cells, heat exchangers, boilers, fluidized beds, cutting-edge innovation, tertiary recovery, chemical separations, the technology of porous ceramic burners, underground feeder cables, water filtration, drug transfer in tissues, thermal insulation, packed-bed energy storage systems, oil and gas flowing in reservoirs[26–30]. Darcy's law is the most popular model for simulating fluid motion in a porous medium. Non-Darcy phenomena are essential for understanding the fluid flow in porous media whenever high velocity is involved i.e. when inertial effects arise. Computational studies deal with the transport in non-Darcian porous medium have stimulated substantial attention by virtue of the ever-growing applications of this field in the twenty-first century. These studies have been examined by using several Newtonian liquids, non-Newtonian liquids, and nanofluids. Mythili et al.[31] presented a mathematical model to explore features of the chemically reactive Casson liquid flow over a plate and cone with the consequence of heat absorption/generation. They noticed that the fluid flow diminishes for augmenting the Casson parameter and Forchheimer number (non-Darcian quadratic drag). Alsabery et al.[32] scrutinized the free convective flow within a porous enclosure of square-shape filled with Al_2O_3-water nanofluid by considering the Brinkman-Forchheimer-extended Darcy model. They concluded that greater porosity of the medium enhances the average Nusselt number. Zehba et al.[33] examined the natural convective Al_2O_3-water nanofluid flow within a V-shaped enclosure containing a heterogeneous porous medium. They detected that higher Darcy number values improve the temperature gradi-

ents around the heated areas and hence increase the average Nusselt number. Shirani and Toghraie[34] numerically analyzed the mixed convective Cu-water nanoliquid flow within a porous cavity with the Forchheimer–Brinkman-extended Darcy model. They determined that with a decrement in Darcy parameter, the Nusselt number rises.

Magnetohydrodynamics (MHD) is the science of the interaction of electro-conductive fluids and magnetic fields. When an electro-conductive fluid crosses a magnetic field flux, an external body force known as the Lorentzian force is generated and this force acts against the fluid flow. Furthermore, the flow may induce magnetic field fluxes[35]. MHD is central to the design of new emerging hybrid electromagnetic fuel cells which are motivated by green, sustainable initiatives. It is a clean technology and circumvents the need for conventional combustion systems in power generation which are ecologically unfriendly. In parallel with laboratory testing of new magnetic fuel cells, numerical simulation of these devices is extremely beneficial for optimizing efficiency and predicting long-term performance. Muthtamilselvan and Doh[36] numerically investigated the mixed convective flow and energy transmission features of different nanofluids within an enclosure with the influence of a magnetic force by adopting a control volume technique. They discovered that the various types of nanofluid flow and energy transmission within the enclosures are highly reliant on the Hartmann and Reynolds numbers. Rashad et al.[37] theoretically scrutinized the MHD free convection flow of a hybrid nanofluid inside an enclosure of triangular-shape by adopting the finite difference method. They found that higher magnetic parameter values cause an augmentation in the Nusselt number. Du et al.[38] utilized the finite difference scheme to explore the MHD free convective $Al_2O_3 - Cu$-water hybrid nanofluid flow in an enclosure and noticed that an increase in magnetic parameter suppresses the effects of thermal buoyancy. Sowmya et al.[39] studied the free convective $Fe_3O_4 - Ag$-water hybrid nanofluid flow and energy transmission characteristics in heated fins attached rectangular enclosure through numerical simulations. They discovered that with high values of the Hartmann number and low values of the Rayleigh number, the flow appears to be laminar. However, at low values of the Hartmann number and high values of the Rayleigh number, they observed the onset of turbulent flow characteristics.

Heat generation or absorption plays an extremely influential role in different phenomena such as high-temperature fuel cell design. For the past few decades, many researchers have been contributing to improve the energy transfers features of nanoliquids inside various cavities. Teamah and Wael[40] numerically scrutinized the free convection flow within a square enclosure with various nanofluids under the impact of uniform heat absorption or generation by utilizing the finite volume method. They demonstrated that the energy transmission is enriched for magnifying the volume fraction values when the heat absorption parameter is frozen with the smaller values. Mliki et al.[41] examined the MHD free convective flow of copper-water nanoliquid within the cavity. They noticed that strengthening the heat generation parameter enhances the energy transmission. Hussain et al.[42] analyzed the thermal

performance of alumina-water nanofluid inside an enclosure under the impact of internal heat absorption or generation by employing the finite element technique. They noticed that the energy transmission and fluid flow are significantly modified with the variations in internal heat absorption or generation parameter. Abdulkadhim et al.[43] numerically explored the natural convective flow of copper-water nanoliquid inside a cavity containing a circular hot cylinder by adopting the Galerkin-weighted residual method.

Most of the studies generally considered the classical Fourier heat flux model. This model has a parabolic formulation for heat conduction and neglects thermal relaxation effects. To accommodate the relaxation rate of the heat flux, the Cattaneo-Christov heat flux model is required which is the non-Fourier hyperbolic conduction model featuring Oldroyd's upper-convected derivative in the Maxwell–Cattaneo equation. In addition, this type of formulation permits the elimination of heat flux by inducing a single equation for the temperature field as performed by Christov[44]. Muhammad et al.[45] deployed the Cattaneo–Christov heat flux model to numerically explore the transport phenomena of mixed convective Ag–ethylene glycol nanoliquid flow inside an enclosure. They exposed that compared to non-Fourier's heat flux model, the rate of heat transfer is higher in the case of Fourier's heat flux model. Jakeer et al.[46] investigated the convective flow characteristics of a hybrid nanoliquid inside an enclosure by using the Cattaneo-Christov heat flux model in the energy equation. Sivasankaran et al.[47] numerically explored the features of convective flow inside an enclosure of square-shape with the Cattaneo-Christov heat flux model. Garia et al.[48] numerically examined the MHD convective $SiO_2 - MoS_2$-water hybrid nanoliquid flow external to cone and wedge geometries with a generalized Cattaneo-Christov heat flux model. They determined that the Fourier's heat flux model estimates higher temperatures than the non-Fourier heat flux model.

To the best of the authors' knowledge, no analysis has been communicated so far to numerically examine the mixed convective energy transmission and flow features of a $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanoliquid within the porous enclosure under the impact of the magnetic field and heat source/sink by adopting the Cattaneo–Christov heat flux model. In practical applications, many factors can enhance the heat transfer. The combination of nanoparticles and base fluids plays a significant role in optimizing the energy transmission features. The novelty of this investigation is to compare and identify the optimum energy transmission and flow features of $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanoliquids within the porous square enclosure. In this analysis, hot sources are considered in the middle of the vertical sidewalls, and cold sinks are considered in the middle of the horizontal sidewalls. The remaining sections of the cavity walls are considered as adiabatic. The Tiwari-Das nanofluid volume fraction model is utilized in this analysis. The non-dimensional governing equations are solved by utilizing the MAC technique[49,50], and the numerical outcomes for streamlines, isotherms, average and local Nusselt numbers are displayed graphically. Validations with previous study are incorporated. It is to be noted

that the deployment of hybrid nanofluids is of immediate relevance to the next generation hybrid electromagnetic fuel cells and may be beneficial to cooling application in nuclear systems, generators, transformers, and electronic devices.

II. MATHEMATICAL FORMULATION

In this section, details are provided for the current mathematical model. Figure. 1 schematically represents the two-dimensional geometry that is to be examined. The MHD mixed convective flow in a square porous cavity saturated with electrically conducting hybrid nanofluids is studied, as a model of a hybrid electromagnetic fuel cell system. The horizontal and vertical walls have length (L). The center parts of the left and right walls are maintained at a high temperature, whereas the center portions of the top and bottom walls are kept at a low temperature. Unsteady, laminar flow of incompressible fluids is considered. The square enclosure includes an isotropic, homogenous, non-deformable porous medium, and non-Darcy behavior is considered. Hybrid nanofluid's thermophysical properties are considered appropriate to the Tiwari-Das model. The flow domain is influenced by a static horizontal externally imposed magnetic field. The influences of internal heat absorption or generation and the non-Fourier thermal relaxation (Cattaneo-Christov heat flux) are considered. The strength of the applied magnetic field is B_0 and it is considered as uniform. It is assumed that the electric field is zero since the ionized fluid's polarization effect is negligible and no external electric field is considered. When the induced electric field is negligible and external electric field is zero, the magnetic Reynolds number is very small. As a consequence, the influence of Hall effect and induced magnetic field are neglected. Further, the variation of thermophysical properties including the viscosity and electrical conductivity is neglected. Furthermore, the considered base fluids (water and kerosene) are Newtonian fluids with low viscosities and the fluids are finitely conducting. So, impact of the viscous dissipation, Joule heating and resistant heating term due to porous medium are neglected.

Based upon the above approximations, the mathematical model features the hybrid nanofluid expressions in the form of the conservation laws of mass, momentum, and energy[36,40,42,45,46,51]:
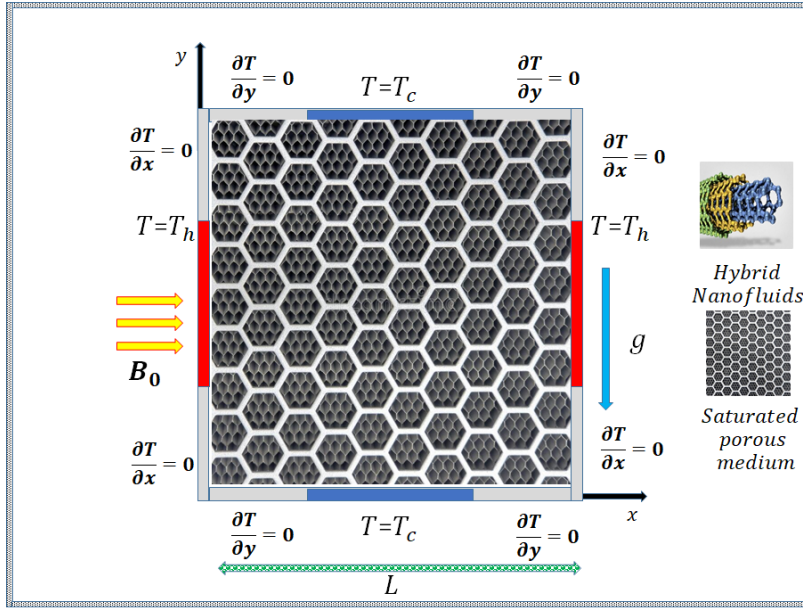

FIG. 1. Flow configuration of the problem.

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \qquad (1)$$

$$\frac{\partial u}{\partial t^*} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} = -\frac{1}{\rho_{hnf}}\frac{\partial p}{\partial x} + \nu_{hnf}\left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right]$$
$$- \frac{\nu_{hnf}}{K}u - \frac{F}{\sqrt{K}}u\sqrt{u^2+v^2} \qquad (2)$$

$$\frac{\partial v}{\partial t^*} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} = -\frac{1}{\rho_{hnf}}\frac{\partial p}{\partial y} + \nu_{hnf}\left[\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2}\right]$$
$$- \frac{\nu_{hnf}}{K}v - \frac{F}{\sqrt{K}}v\sqrt{u^2+v^2}$$
$$+ \frac{(\rho\beta)_{hnf}}{\rho_{hnf}}g(T-T_c) - \frac{\sigma_{hnf}B_0^2}{\rho_{hnf}}v \qquad (3)$$

$$\frac{\partial T}{\partial t^*} + u\frac{\partial T}{\partial x} + v\frac{\partial T}{\partial y} = \frac{k_{hnf}}{(\rho C_p)_{hnf}}\left[\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right] + \frac{Q_0}{(\rho C_p)_{hnf}}(T-T_c)$$
$$- \delta\left(u\frac{\partial u}{\partial x}\frac{\partial T}{\partial x} + v\frac{\partial v}{\partial y}\frac{\partial T}{\partial y} + u^2\frac{\partial^2 T}{\partial x^2} + v^2\frac{\partial^2 T}{\partial y^2}\right)$$
$$- \delta\left(2uv\frac{\partial^2 T}{\partial x\partial y} + u\frac{\partial v}{\partial x}\frac{\partial T}{\partial y} + v\frac{\partial u}{\partial y}\frac{\partial T}{\partial x}\right) \qquad (4)$$

The initial-boundary conditions imposed on the enclosure's walls are given in Table 1.

Hybrid nanofluid's thermophysical properties are necessary for enhancing the energy transfer. The mono and hybrid nanofluids thermophysical properties are assumed appropriate to the Tiwari-Das model and are represented as follows[52]:

Table 2 summarizes the thermophysical properties of the base fluids and nanoparticles[53,54].

The subsequent non-dimensional quantities are defined to simplify the equations (1)–(4) toward the non-dimensional form:

$$U = \frac{u}{U_0}; V = \frac{v}{U_0}; X = \frac{x}{L}; Y = \frac{y}{L};$$

$$P = \frac{p}{\rho_{hnf}U_0^2}; \theta = \frac{T-T_c}{T_h-T_c}; t = \frac{t^* U_0}{L} \qquad (5)$$

By virtue of Eqn. (5), the subsequent governing equations appear in the dimensionless form:

$$\frac{\partial U}{\partial X} + \frac{\partial V}{\partial Y} = 0 \qquad (6)$$

$$\frac{\partial U}{\partial t} + U\frac{\partial U}{\partial X} + V\frac{\partial U}{\partial Y} = -\frac{\partial P}{\partial X} + \left(\frac{\nu_{hnf}}{\nu_f}\right)\frac{1}{Re}\left[\frac{\partial^2 U}{\partial X^2} + \frac{\partial^2 U}{\partial Y^2}\right]$$
$$- \left(\frac{\nu_{hnf}}{\nu_f}\right)\frac{1}{Re\,Da}U - \frac{F}{\sqrt{Da}}U\sqrt{U^2+V^2} \qquad (7)$$

$$\frac{\partial V}{\partial t} + U\frac{\partial V}{\partial X} + V\frac{\partial V}{\partial Y} = -\frac{\partial P}{\partial Y} + \left(\frac{\nu_{hnf}}{\nu_f}\right)\frac{1}{Re}\left[\frac{\partial^2 V}{\partial X^2} + \frac{\partial^2 V}{\partial Y^2}\right]$$
$$- \left(\frac{\nu_{hnf}}{\nu_f}\right)\frac{1}{Re\,Da}V - \frac{F}{\sqrt{Da}}V\sqrt{U^2+V^2} + \frac{(\rho\beta)_{hnf}}{\rho_{hnf}\beta_f}Ri\,\theta$$
$$- \left(\frac{\rho_f}{\rho_{hnf}}\right)\left(\frac{\sigma_{hnf}}{\sigma_f}\right)\frac{Ha^2}{Re}V \qquad (8)$$

$$\frac{\partial\theta}{\partial t} + U\frac{\partial\theta}{\partial X} + V\frac{\partial\theta}{\partial Y} = \left(\frac{\alpha_{hnf}}{\alpha_f}\right)\frac{1}{Re\,Pr}\left[\frac{\partial^2\theta}{\partial X^2} + \frac{\partial^2\theta}{\partial Y^2}\right]$$
$$+ \left(\frac{\alpha_{hnf}}{\alpha_f}\right)\frac{Q}{Re\,Pr}\theta - \delta_e\left(U\frac{\partial U}{\partial X}\frac{\partial\theta}{\partial X} + V\frac{\partial V}{\partial Y}\frac{\partial\theta}{\partial Y} + U^2\frac{\partial^2\theta}{\partial X^2} + V^2\frac{\partial^2\theta}{\partial Y^2}\right)$$
$$- \delta_e\left(2UV\frac{\partial^2\theta}{\partial X\partial Y} + U\frac{\partial V}{\partial X}\frac{\partial\theta}{\partial Y} + V\frac{\partial U}{\partial Y}\frac{\partial\theta}{\partial X}\right) \qquad (9)$$

The relevant dimensionless parameters featured in Eqns. (7)-(9) are summarized in Table 3. The transformed dimensionless boundary conditions associated with Eqns. (6)-(9) are listed in Table 4.

Nusselt number: The local and mean Nusselt numbers (wall heat transfer rate) are given by the subsequent expressions:

$$Nu = -\frac{k_{hnf}}{k_f}\left(\frac{\partial\theta}{\partial Y}\right)_{Y=0} \qquad (10)$$

$$Nu_{avg} = \int_0^1 Nu\,dX \qquad (11)$$

TABLE I. The dimensional form of initial-boundary conditions[21,47].

Initial condition $t^* \leq 0$, $0 \leq x \leq L$, $0 \leq y \leq L$:	$u = v = 0$	$T = T_c$
Left wall $t^* > 0$, $x = 0$:	$u = v = 0$,	$\frac{\partial T}{\partial x} = 0$ for $0 \leq y \leq 0.25L$
	$0 \leq y \leq L$:	$T = T_h$ for $0.25L \leq y \leq 0.75L$
		$\frac{\partial T}{\partial x} = 0$ for $0.75L \leq y \leq L$
Right wall $t^* > 0$, $x = L$:	$u = v = 0$,	$\frac{\partial T}{\partial x} = 0$ for $0 \leq y \leq 0.25L$
	$0 \leq y \leq L$:	$T = T_h$ for $0.25L \leq y \leq 0.75L$
		$\frac{\partial T}{\partial x} = 0$ for $0.75L \leq y \leq L$
Bottom wall $t^* > 0$, $y = 0$:	$u = v = 0$,	$\frac{\partial T}{\partial y} = 0$ for $0 \leq x \leq 0.25L$
	$0 \leq x \leq L$:	$T = T_c$ for $0.25L \leq x \leq 0.75L$
		$\frac{\partial T}{\partial y} = 0$ for $0.75L \leq x \leq L$
Top wall $t^* > 0$, $y = L$:	$u = v = 0$	$\frac{\partial T}{\partial y} = 0$ for $0 \leq x \leq 0.25L$
	$0 \leq x \leq L$:	$T = T_c$ for $0.25L \leq x \leq 0.75L$
		$\frac{\partial T}{\partial y} = 0$ for $0.75L \leq x \leq L$

TABLE II. Thermo-physical properties of water, kerosene, Fe_3O_4 and $MWCNT$.[53,54]

Property	Water	Kerosene	Fe_3O_4	MWCNT
$\rho(kgm^{-3})$	997.1	780	5200	1600
$C_p(Jkg^{-1}K^{-1}$	4179	2090	670	796
$k(Wm^{-1}k^{-1})$	0.613	0.149	6	3000
$\beta(K^{-1})$	21×10^{-5}	99×10^{-5}	1.3×10^{-5}	4.2×10^{-5}
$\sigma(\Omega^{-1}m^{-1})$	0.05	6×10^{-10}	25×10^3	4.8×10^{-7}
$\mu(kgm^{-1}s^{-1})$	8.9×10^{-4}	1.64×10^{-3}	-	-

TABLE III. Dimensionless parameters

Reynolds number	$Re = \frac{U_0 L}{\nu_f}$
Grashof number	$Gr = \frac{g\beta_f(T_h - T_c)L^3}{\nu_f^2}$
Prandtl number	$Pr = \frac{\nu_f}{\alpha_f}$
Hartmann number	$Ha = B_0 L\sqrt{\frac{\sigma_f}{\mu_f}}$
Richardson number	$Ri = \frac{Gr}{Re^2}$
Heat generation/absorption coefficient	$Q = \frac{Q_0 L^2}{(\rho C_p)_{hnf} \alpha_{hnf}}$
Darcy number	$Da = \frac{K}{L^2}$
Cattaneo-Christov heat flux parameter	$\delta_e = \frac{\delta U_0}{L}$

III. MAC SOLUTION AND VALIDATION OF MAC RESULTS

The MAC method is used to solve the Eqns. (7)-(9) with non-dimensional initial-boundary conditions as stated in Table 4. The detailed explanation about the MAC procedure is found in the references.[21,49,50,55,56] The discretization form of momentum and energy equations are presented as follows.
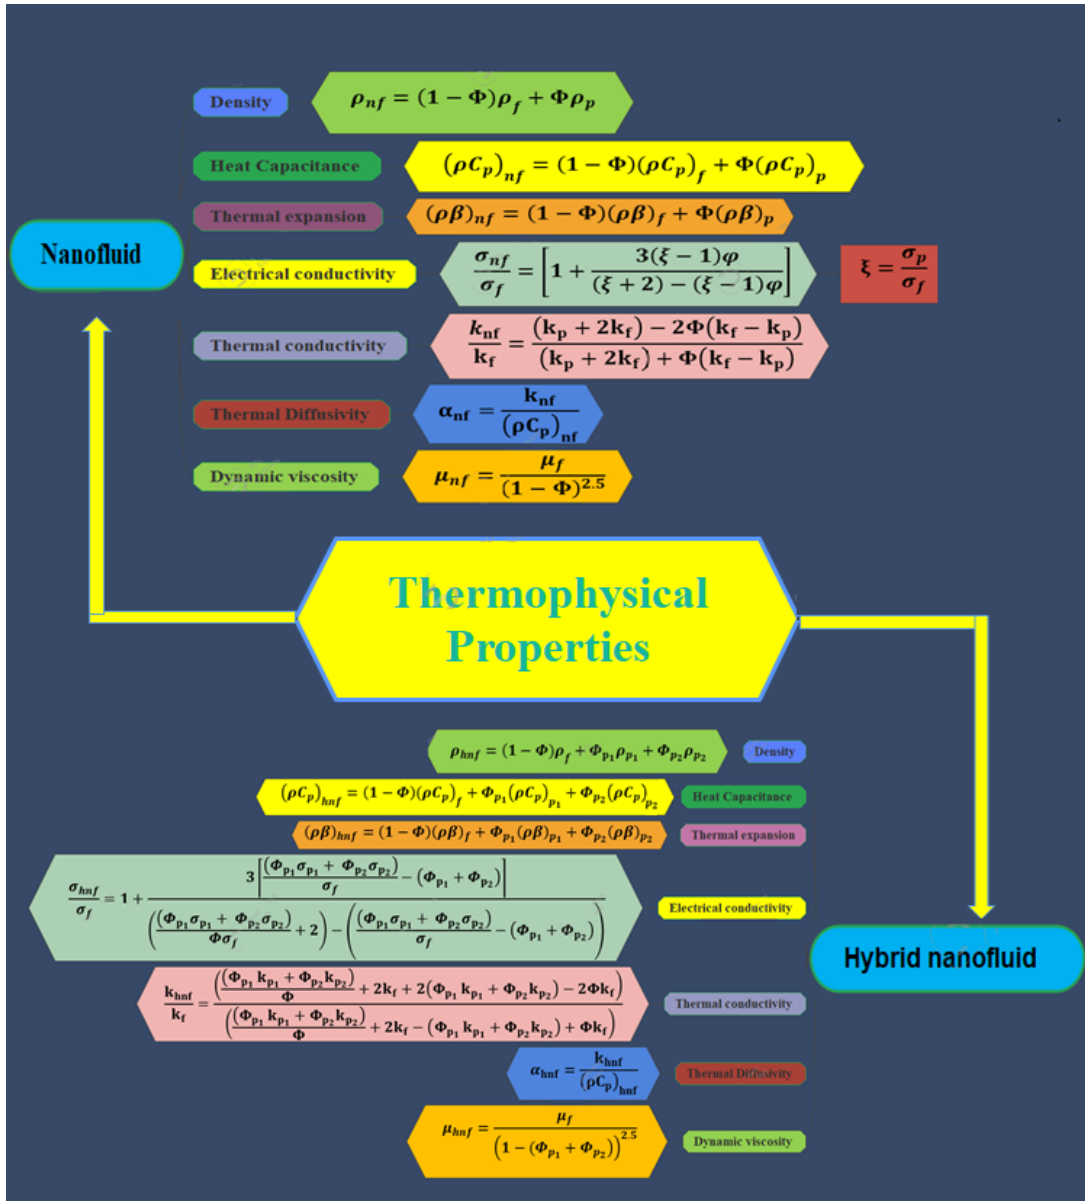

FIG. 2. Thermophysical properties of mono and hybrid nanofluids[52]

The X-momentum equation is discretized as:

$$U^{n+1} = U^n + \left(-\left[U\frac{\partial U}{\partial X} + V\frac{\partial U}{\partial Y} \right] + A_1 \left[\frac{\partial^2 U}{\partial X^2} + \frac{\partial^2 U}{\partial Y^2} \right] \right) dt$$
$$- \left(A_2 U + A_3 \, U \sqrt{U^2 + V^2} \right) dt. \tag{12}$$

The Y-momentum equation is discretized as:

$$V^{n+1} = V^n + \left(-\left[U\frac{\partial V}{\partial X} + V\frac{\partial V}{\partial Y} \right] + A_1 \left[\frac{\partial^2 V}{\partial X^2} + \frac{\partial^2 V}{\partial Y^2} \right] \right) dt$$
$$- \left(A_2 V - A_4 \, \theta + A_3 \, V\sqrt{U^2 + V^2} + A_5 V \right) dt. \tag{13}$$

The discretized energy equation to obtain the next time level (θ^{n+1}) is acquired as follows:

$$\theta^{n+1} = \theta^n + \left(-\left[U\frac{\partial \theta}{\partial X} + V\frac{\partial \theta}{\partial Y} \right] + A_6 \left[\frac{\partial^2 \theta}{\partial X^2} + \frac{\partial^2 \theta}{\partial Y^2} + Q\theta \right] \right) dt$$
$$- \left[\delta_e \left(U\frac{\partial U}{\partial X}\frac{\partial \theta}{\partial X} + V\frac{\partial V}{\partial Y}\frac{\partial \theta}{\partial Y} + U^2\frac{\partial^2 \theta}{\partial X^2} + V^2\frac{\partial^2 \theta}{\partial Y^2} \right) \right] dt$$
$$- \left[\delta_e \left(2UV\frac{\partial^2 \theta}{\partial X \partial Y} + U\frac{\partial V}{\partial X}\frac{\partial \theta}{\partial Y} + V\frac{\partial U}{\partial Y}\frac{\partial \theta}{\partial X} \right) \right] dt. \tag{14}$$

where, $A_1 = \left(\frac{\nu_{hnf}}{\nu_f} \right) \frac{1}{Re}$, $A_2 = \left(\frac{\nu_{hnf}}{\nu_f} \right) \frac{1}{ReDa}$ $A_3 = \frac{F}{\sqrt{Da}}$, $A_4 = \frac{(\rho\beta)_{hnf}}{\rho_{hnf}\beta_f} \, Ri$, $A_5 = \left(\frac{\rho_f}{\rho_{hnf}} \right) \left(\frac{\sigma_{hnf}}{\sigma_f} \right) \frac{Ha^2}{Re}$, $A_6 = \left(\frac{\alpha_{hnf}}{\alpha_f} \right) \frac{1}{Re\,Pr}$.

TABLE IV. The dimensionless initial-boundary conditions[21,47]

Initial condition $t \leq 0$, $0 \leq X \leq 1$, $0 \leq Y \leq 1$:	$U = V = 0$	$\theta = 0$
Left wall $t > 0$, $X = 0$:	$U = V = 0$,	$\frac{\partial \theta}{\partial X} = 0$ for $0 \leq Y \leq 0.25$
	$0 \leq Y \leq 1$:	$\theta = 1$ for $0.25 \leq Y \leq 0.75$
		$\frac{\partial \theta}{\partial X} = 0$ for $0.75 \leq Y \leq 1$
Right wall $t > 0$, $X = 1$:	$U = V = 0$,	$\frac{\partial \theta}{\partial X} = 0$ for $0 \leq Y \leq 0.25$
	$0 \leq Y \leq 1$:	$\theta = 1$ for $0.25 \leq Y \leq 0.75$
		$\frac{\partial \theta}{\partial X} = 0$ for $0.75 \leq Y \leq 1$
Bottom wall $t > 0$, $Y = 0$:	$U = V = 0$,	$\frac{\partial \theta}{\partial Y} = 0$ for $0 \leq X \leq 0.25$
	$0 \leq X \leq 1$:	$\theta = 0$ for $0.25 \leq X \leq 0.75$
		$\frac{\partial \theta}{\partial Y} = 0$ for $0.75 \leq X \leq 1$
Top wall $t > 0$, $Y = 1$:	$U = V = 0$	$\frac{\partial \theta}{\partial Y} = 0$ for $0 \leq X \leq 0.25$
	$0 \leq X \leq 1$:	$\theta = 0$ for $0.25 \leq X \leq 0.75$
		$\frac{\partial \theta}{\partial Y} = 0$ for $0.75 \leq X \leq 1$

To demonstrate the accuracy of the MAC numerical scheme, the present outcomes are compared with Khan et al.[50] in a special case. The hybrid nanofluid's thermophysical properties, magnetic field, heat source/sink, and Cattaneo Christov heat flux, are considered to be absent, the thermal radiation is considered to be present, and adequate adjustments are made in the initial and boundary conditions of the current model to compare the current outcomes with the results presented by Khan et al.[50]. One can observe from Figure 3 that the current MAC results which are illustrated through the streamlines and isotherms contours express a substantial agreement with the outcomes of Khan et al.[50]. This validates the accurateness of the current outcomes.

IV. RESULT AND DISCUSSION

In this section, the MAC numerical results (contour plots and graphs) are presented and scrutinized for the magneto-hydrodynamic free convection inside a square porous enclosure filled with the $Fe_3O_4 - MWCNT-$water or $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid with heat sink/source and Cattaneo–Christov heat flux. The range of key parameters is specified as follows: volumetric heat genera-

tion/absorption coefficient ($-5 \leq Q \leq 15$), nanoparticle volume fraction ($0.01 \leq \phi \leq 0.05$), Richardson number ($10^{-2} \leq Ri \leq 10$), Darcy number ($10^{-3} \leq Da \leq 10^{-1}$), Reynolds number ($1 \leq Re \leq 5$), Hartmann number ($0 \leq Ha \leq 50$), and Prandtl number ($Water = 6.8$ & $Kerosene = 21.003$). The following default values are employed throughout the simulations: $Re = 5$, $Q = -5$, $Da = 10^{-3}$; $Ha = 10$, $\phi = 0.05$, $Ri = 1$, and $\delta_e = 0.01$, unless otherwise specified. This data correlates as closely as possible to the actual operational characteristics of hybrid electromagnetic fuel cells by deploying the hybrid nanofluids[54,57,58]. Figures $4 - 21$ portray the outcomes of these parameters on average heat transfer rate, local heat transfer rate, streamlines, isotherms, U and V velocity profiles. Further, the average Nusselt number distribution is demonstrated in Tables $5 - 6$.

A. Investigating the streamlines and isotherms profiles under the consequence of Reynolds number

In fluid mechanics, the Reynolds number is a dimensionless quantity that estimates the proportion of inertia force to viscous force. This ratio is influenced by different factors, including the fluid velocity variations. The Reynolds number
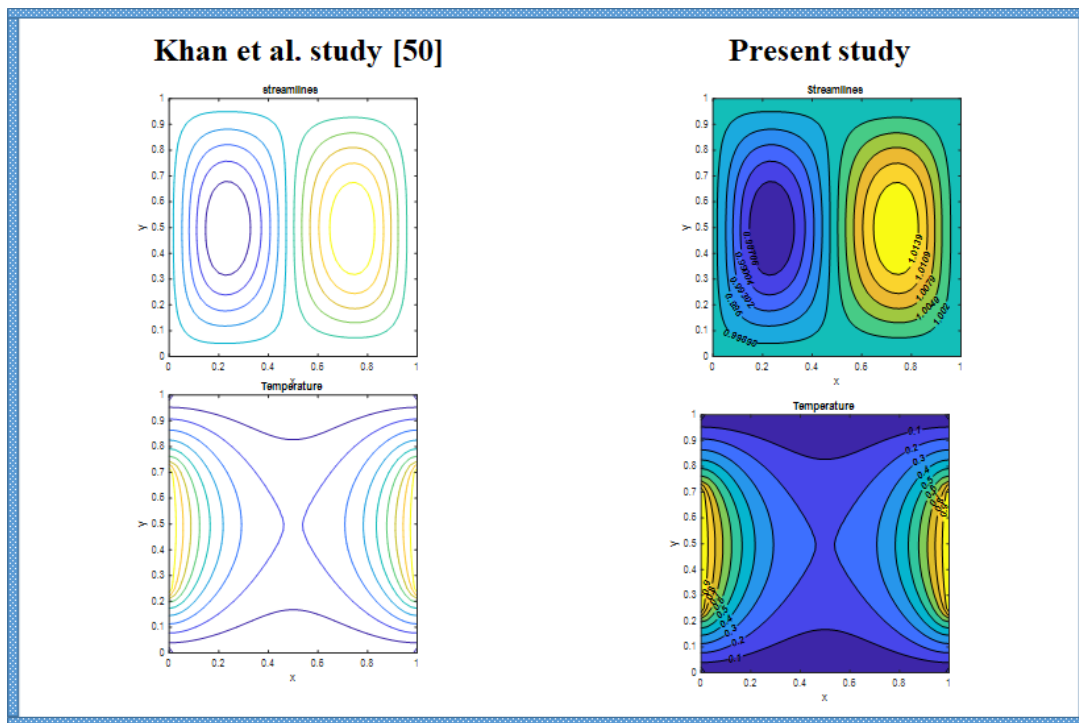

FIG. 3. Comparative contour plots with $Gr = 10^4$, $Re = 10$, $Pr = 0.71$, $Da = 10^{-2}$, $Nr = 1$.[50]

helps to predict the flow patterns in various flow situations. Higher Reynolds numbers represent the turbulent flow while the lower Reynolds numbers represent the laminar flow. The Reynolds number is one of the important pertinent parameters in fluid mechanics. Figure 4 shows the streamline distributions inside the square enclosure with different Reynolds number (Re) for both $Fe_3O_4 - MWCNT-$water (Fig. 4-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 4-II) hybrid nanofluids. The values of the inner circulation cells gradually increase and the flow is more elevated at the top and bottom of the cavity when the values of Reynolds number are magnified. In Fig. 4-I, dual circulation cells are formed in case of $Fe_3O_4 - MWCNT-$water hybrid nanofluid when $Re = 1$. For the higher values of Reynolds number, the circulating cells are stretched along the vertical direction, and higher circulations are observed at bottom and top of the enclosure. However, in the center of the cavity, the flow is reduced. In $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, when $Re = 1$, the dual circulation cells are formed inside the enclosure. When the Reynolds number is augmented from $Re = 1$ to $Re = 3$, the circulating cells are fragmented. This implies that velocity of the hybrid nanofluid is reduced at the middle part of the enclosure and the fluid velocity is increased at the bottom and top of the enclosure. For the higher values of Reynolds number, the inner circulating cells are broken into two portions and slightly move towards the top and bottom walls of the cavity. As a result, it is notable that in the case of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid, stronger circulation is observed at the top and bottom regions of the cavity and the flow velocity decreases at the center of the cavity.

Figure 5 elucidates the isotherms of $Fe_3O_4 - MWCNT-$water (Fig. 5-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 5-II) hybrid nanofluids within the cavity for various values of Reynolds number. As seen in Fig. 5 (I-A), energy transfer inside the cavity is suppressed with a cooler central zone when $Re = 1$. The effect of the cold slits is dominant in the center of the cavity whereas the impact of hot slits is explored only in their neighborhoods. When $Re = 3$, the influence of the hot slits and cold slits is relatively same inside the cavity as shown in Fig. 5 (I-B). When $Re = 5$, the influence of the hot slits is dominant in the center of the cavity whereas the impact of cold slits is explored only in their neighborhoods. The results indicate that the energy transfer is considerably improved for augmenting the Reynolds number. The heat transfer analysis of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is demonstrated in Fig. 5 (II). It is observed that the influence of the hot slits and cold slits is relatively same inside the cavity when $Re = 1$. For increasing the value of Reynolds number from $Re = 1$ to $Re = 3$, the heat transfer is increased in the middle part of cavity as shown in Fig. 5 (II-B). Increasing the values of Reynolds number from $Re = 3$ to $Re = 5$ has the tendency to significantly explore the impact of the hot slits throughout the cavity except the neighborhood of cold slits. This indicates that the heat transfer improves for enhancing the Reynolds number values. The influence of the hot slits is more prominent with more elevated values of Reynolds number.

B. Investigating the effect of the magnetic field of hybrid nanofluids on streamlines, isotherms, U and V velocity profiles

When the applied magnetic field interacts with the electrically conducting fluid, a magnetic force known as the Lorentz force is formed, which affects fluid velocity. In the theoretical analysis of such flows, a dimensionless variable known as the Hartmann number arises which represents the ratio of the magnetic force to viscous force. Figure 6 represents the significance of the Hartmann number values on streamline contours for $Fe_3O_4 - MWCNT-$water (Fig. 6-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 6-II) hybrid nanofluids. The magnetic field effect is featured in the Y-momentum ($Eqn.(8)$) through the term $\frac{\rho_f}{\rho_{hnf}} \frac{\sigma_{hnf}}{\sigma_f} \frac{Ha^2}{Re}$. An increase in the values of the Hartmann number boosts the magnetic body force and strongly modifies the inner circulating cells' strength and contour substantially for both hybrid nanofluids. When $Ha = 0$ (in the absence of the magnetic field), the flow circulates freely inside the square cavity. In this case, a single left and right circulation cells are formed for $Fe_3O_4 - MWCNT-$water hybrid nanofluid. The inner circulation cell forms a peanut shell shaped structure. When $Ha = 10$, there is no change in the shape of the circulating cells but the magnitudes of the stronger circulation cells slightly diminish. When $Ha = 50$, the inner circulating cells are divided into two parts and the magnitudes of the circulating cells are diminished. This elucidates that an augmentation in the Hartmann number causes a deceleration in the fluid flow. As seen in Fig. 6 (II-A), double right and left circulation cells form for $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid when $Ha = 0$. There is no significant change in the streamlines of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid for magnifying the Hartmann number from $Ha = 0$ to $Ha = 10$. Rising the Hartmann number to $Ha = 50$ makes notable change in the eddies. The two eddies emerge at the bottom and top of the cavity walls as shown in Fig. 6(II-C). For the increased values of the Hartmann number, the stronger circulation cell's shapes are slightly changed and more inner circulation cells form at the top and bottom of the cavity. The center of the cavity has less flow; the left circulation cells are entirely broken into two separate circulation cells and the inner layers of the right circulating cells are separated. This means that the fluid velocity is reduced in the middle of the enclosure while it is increased at the bottom and top. That is, the magnetic force suppresses and weakens the circulating cells as the Hartmann number increases. It is noticed from Figs. (6-I) and (6-II) that the impact of magnetic field on $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is stronger than $Fe_3O_4 - MWCNT-$water hybrid nanofluid. There is clearly an interplay between the magnetic and viscous forces which produce different effects in the $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids, and this is attributable to viscosity differences in the base fluids.

Figure 7 represents the significance of the Hartmann number on isotherm contours for $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids. For both hybrid nanofluids considerable heat transfer is observed at the center of the cavity. The higher heat transmission is observed near the right and left hot slits in case of $Fe_3O_4 - MWCNT-$water. Higher heat transfer is observed throughout the cavity except the neighborhoods of the cold slits in $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case. Although some kinetic energy is dissipated as thermal energy by dragging the nanofluid against the action of the transverse magnetic field, there is no significant heat transfer modification in both hybrid nanofluids for increasing values of the magnetic parameter. On comparing Figs. 7(I) and 7(II), the heat transfer is greater in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case. In addition, the impact of hot slits is stronger in $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$water hybrid nanofluid.

Figure 8 shows the U velocity profiles of $Fe_3O_4 - MWCNT-$water (Fig. 8-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 8-II) hybrid nanofluids for different values of the Hartmann number. By increasing the Hartmann parameter from 0 to 10, insignificant changes are obtained in both hybrid nanofluid cases. In the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case, when $Ha = 0$ and $Ha = 10$, the contour lines are densely formed near the horizontal walls and a single circulation cell is formed near the center of the vertical walls. By enhancing the values from 10 to 50, considerable changes are observed. In this case, the contour lines are shrunk near the horizontal walls whereas more circulation cells are formed at the center of the cavity. In the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, the contour lines are densely formed near the horizontal walls of the cavity for all the considered values of Ha. At the center portion, when $Ha = 0$ and $Ha = 10$, more circulation cells are formed along the secondary diagonal zone whereas more circulation cells are formed along the principal diagonal zone in the case of $Ha = 50$. Overall, an increase in Ha slightly enhances the circulation at the center.

Figure 9 illustrates the V velocity profiles of $Fe3O4 - MWCNT-$Water (Fig. 9-I) and $Fe3O4 - MWCNT-$kerosene (Fig. 9-II) hybrid nanofluids for various values of the magnetic parameter. As seen in Fig. 9(I-A), combined circulation cells are formed at the middle portion when $Ha = 0$. When $Ha = 10$, the inner contour line shrinks at the middle portion. When $Ha = 50$, the inner cells are split and moved towards the top and bottom zones. This indicates that improving the magnetic parameter reduces the velocity at the center and increases near the horizontal walls. It is noticed from Fig. 9(II-A) that stronger circulation cells are formed close to the vertical walls when $Ha = 0$. When $Ha = 10$, the stronger circulation cells slightly shrink at the middle portion but the weaker circulation cells are densely formed at the center of the cavity. When high magnetic field ($Ha = 50$) is imposed, the stronger circulation cells near the vertical wall are split into two parts and slightly move towards the horizontal walls and the dense of the inner contour lines is decreased, as seen in Fig. 9(II-C). Therefore, an increase in the values of the magnetic parameter reduces the V-velocity profiles in the center of the cavity.

C. Investigating the consequence of Darcy on streamlines and isotherms

The Darcy number (Da) quantifies the effect of porous medium's permeability (K) on the percolating nanofluid. A reduction in K means an increase in flow resistance. This porous solid matrix's fiber structure significantly affects the fluid flow characteristics and considerably affects the heat transfer characteristics. The Darcy parameter arises in both primary and secondary momentum equations $(Eqns.(7)$ and $(8))$ through the linear Darcy drag force terms, $\frac{-v_{hnf}}{v_f} \frac{1}{ReDa} U$ and $\frac{-v_{hnf}}{v_f} \frac{1}{ReDa} V$. In this study, permeability of the porous matrix is considered based on the physically attainable range $(10^{-3} \leq Da \leq 10^{-1})$. Figure 10 displays the Darcy parameter's influence on streamlines distribution of $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids. As seen, the circulating cells in the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case are created along the center portion of the cavity whereas the circulating cells in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case are divided into two eddies and are formed at the bottom and top of the enclosure. Enhancing values of the Darcy number modify the inner circulation cells gradually and the flow is increased at the center of the cavity in the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case. The inner circulating cells are enlarged and extended towards the center of the enclosure in $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case. This shows that increasing values of Darcy parameter increase the fluid flow inside the enclosure.

Figure 11 demonstrates the influences of the Darcy number on isotherm contours for $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids. In the contour plots, for both hybrid nanofluids, significant heat transfer is observed at center of the cavity i.e. thermal diffusion is intensified in the central zone of the cavity. In case of $Fe_3O_4 - MWCNT-$water hybrid nanofluid, higher temperature contour's magnitude is observed near the right and left hot slits as shown in Fig. 11(I). In $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case stronger heat transfer is observed throughout the cavity and more variations in the heat transfer are noticed near the cold slits. Comparing Figs. 11(I) and 11(II), more efficient thermal transport arises in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case in which a warmer (yellow) central zone is consistently visible whereas in the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case, slightly cooler (dark orange) central zones are observed.

D. Investigating the consequence of heat absorption and generation on streamlines, isotherms, U and V velocity profiles

A heat sink is a passive heat exchanger that transmits the heat produced by a mechanical or electronic devices into a coolant fluid in motion. A heat source is an object that produces or radiates heat. It should be emphasized that $Q < 0$ signifies the internal heat sink (absorption) whereas $Q > 0$ characterizes the internal heat source (generation). Figure

12 illustrates the impacts of heat absorption/generation (Q) on the streamlines for $Fe_3O_4 - MWCNT-$water (Fig. 12-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 12-II) hybrid nanofluids. In the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case with heat sink $(Q = -5)$ impact, there are two parallel elongated vertical cells which are distributed in the enclosure. For the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, there are four cells on which two cells are formed in the right and other two cells are formed in the left half spaces of the cavity when a heat sink is present $(Q = -5)$. In the scarcity of heat absorption/generation $(Q = 0)$ parameter, in the $Fe_3O_4 - MWCNT-$water case, the inner circulation cells are split and moved towards the bottom and top of the enclosure. The circulation cells shrink at the center of the cavity in $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case. The fluid flow is restricted in the cavity compared to the sink case for both hybrid nanofluids. In the heat generation case, $(Q = 15)$ case, the cell structure is further modified. For the $Fe_3O_4 - MWCNT-$water hybrid case, two further cells form and now six circulation cells are observed. The circulation cells with low intensity form at the top-left, middle-right and lower-left corner of the enclosure while stronger circulation cells form at the top-right, middle-left and lower-right corner of the enclosure. For the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, although six cells are present, the central cells are much weaker and not fully formed. The upper and lower pairs of circulation cells are however quite strong with intense flow in the top-right and lower-right corners of the enclosure.

Figure 13 illustrates the influence of heat absorption/generation (Q) on the isotherms for $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids. The modifications in the heat absorption/generation characteristics have a notable impact on heat transfer characteristics inside the cavity. The features of heat absorption/generation parameters on the isotherms of $Fe_3O_4 - MWCNT-$water hybrid nanofluid is shown in Fig. 13-I. As shown, the influence of the hot slits is low at the center zone of the cavity in the case of heat sink $(Q = -5)$. In the absent of the internal heat absorption/generation $(Q = 0)$, the influence of the hot slits is extended towards the cavity's center region. When the heat source $(Q = 15)$ is present, the influence of the hot slits is highly noticeable in the center zone and more heat transfer occurs in the middle of the cavity. Figure (13-II) shows that larger hot zone region arises in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case. The hot region is sustained in the majority of the cavity and indicating an elevation in heat transfer throughout the cavity. Compared to the heat sink case, the hot region is more extended in the absence of heat sink/source. The deployment of a heat source significantly improves the magnitudes of the isotherms and thereby the energy transfer inside the cavity is enhanced. The influence of heat sink/source is considerably greater in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$water hybrid nanofluid. However, the impact of heat sink/source elucidates higher variations in case of $Fe_3O_4 - MWCNT-$water hybrid nanofluid. As seen in figures (13-I) and (13-II), the variations in the heat sink and source parameter effectively modify the heat transfer in both

hybrid nanofluids.

Figure 14 shows the U velocity profiles of $Fe_3O_4 - MWCNT-$water (Fig. 14-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 14-II) hybrid nanofluids for different values of heat source/sink coefficient (Q). When $Q = -5$, the contour lines are densely formed near the horizontal walls and a single circulation cell is formed near the center of the vertical walls. When $Q = 0$, the contour lines are shrunk near the top horizontal walls whereas few circulation cells are formed at the center of the cavity. When $Q = 15$, the contour lines are further shrunk near the horizontal walls whereas more circulation cells are formed at the center of the cavity. In the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, the contour lines are densely formed near the horizontal walls of the cavity for all the considered values of Q. When increasing the values of Q, more circulation cells are formed at the middle of cavity. Overall, an increase in Q slightly enhances the circulation at the center.

Figure 15 illustrates the V velocity profiles of $Fe_3O_4 - MWCNT-$water (Fig. 15-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 15-II) hybrid nanofluids for various values of heat source/sink coefficient (Q). As seen in Fig. 15(I-A), combined circulation cells are formed at the middle portion when ($Q = -5$). When ($Q = 0$), the inner cells are split and moved towards the top and bottom zones. When ($Q = 15$), stronger circulation cells are noticed inside the cavity but weaker circulation cells are noticed near the center of the vertical and horizontal walls. As seen, fluid circulation is very high in the presence of heat source. It is noticed from Fig. 15(II-A) that stronger circulation cells are formed close to the vertical walls when ($Q = -5$). When ($Q = 15$), the stronger circulation cells near the vertical wall are split into two parts and slightly move towards the horizontal walls and the dense of the inner contour lines is decreased, as seen in Fig. 15(II-C). Overall, an enhancement in the values of the heat source/sink coefficient Q increases the V-velocity profiles in the center of the cavity.

E. Investigating the streamline profiles under the consequence of Richardson number

Figure 16 portrays the forced convective (A), mixed convective (B), and natural convective (C) fluid flow characteristics of both $Fe_3O_4 - MWCNT-$water (Fig. 16-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 16-II) hybrid nanofluids. The convective transportation within the cavity is greatly influenced by the Richardson number. The Richardson number represents the connection between the buoyancy effects and shear force and is expressed as $Ri = \frac{Gr}{Re^2}$. Higher Richardson numbers indicate the natural convective flow ($Ri > 1$), lower Richardson numbers indicate the forced convective flow ($Ri < 0.1$), and $Ri = 1$ describes the pure mixed convective flow. The thermal buoyancy term $\frac{\rho\beta_{hnf}}{\rho_{hnf}\beta_f}Ri\theta$ contains the Richardson number and it is considered in the secondary momentum equation ($Eqn.8$). Figure 16 (I-A) visualizes the development of streamlines for $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - $

$MWCNT-$kerosene hybrid nanofluids flow in the case of natural convection i.e. $Ri = 10$. In the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case, more circulating cells are formed in the proximity of the right wall with strong flow movement in the middle core region of the enclosure. On the other hand, in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, the circulating cells have separated into two different eddies and are created along the cavity's top and bottom walls. As a result, in the middle of the cavity, there is less flow. The contour shapes are not noticeably modified when Ri is improved from 0.01 to 1 (i.e. forced convective flow to mixed convective flow) for both hybrid nanofluids. This reveals that even in the case of mixed convection, the forced convective flow behavior is maintained consistently. When $Ri = 10$, the magnitudes of the interior vortices are increased for both nanofluids as shown in Figure 16(C). The magnitude of streamline contours is more elevated in $Fe_3O_4 - MWCNT-$water hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid. Further, a dual eddy pair is noticed inside the enclosure for the $Fe_3O_4 - MWCNT-$water hybrid nanofluid whereas a quadruple eddy structure is observed with the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid for any value of Richardson number. This indicates that higher velocity is observed in $Fe_3O_4 - MWCNT-$water hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid.

F. Investigating the effect of the volume fraction of hybrid nanoparticles on streamlines and isotherms

The fluid's ability to transfer the heat is mainly governed by its thermal conductivity. The addition of nanoparticles has the tendency to enhance the thermal conductivity of the carrying fluid. In addition, the proper combination of different variety of nanoparticles further augments the thermal conductivity of the carrying fluid. As a result, the behavior of streamlines of the hybrid nanofluids is modified for increasing the volume fraction of the hybrid nanoparticles. It is to be noted that the impact of volume fraction is analyzed by fixing the heat sink/source parameter value as $Q = 15$ (heat source). Figure 17 demonstrates the streamlines of $Fe_3O_4 - MWCNT-$water (Figure 17-I) and $Fe_3O_4 - MWCNT-$kerosene (Figure 17-II) hybrid nanofluids. In the $Fe_3O_4 - MWCNT-$water hybrid nanofluid case, circulation cells form throughout the cavity, with stronger flow synthesizes along the corners of right-side wall and the center of left-side wall. In the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, the circulating cells form in the corners of the enclosure, the stronger flow synthesizes along the corners of right-side wall, and the minimum number of circulation cells is formed in the center of the right and left walls. This implies that an insignificant flow is noticed in the core zone of the cavity in the case of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid. Figure (17-I) shows that for increasing the values of ϕ, the shape of the stronger circulation cells enlarges whereas the weaker circulation cells shrink. These changes are more noticeable for increasing the volume fraction from $\phi = 0.03$ to $\phi = 0.05$. Therefore, the flow circulation inside

the cavity is increasing for increasing the volume fraction. Figure (17-II) explores that for increasing the values of volume fraction (ϕ), the magnitudes of the weaker circulation cells are slightly increased whereas there is no variation in the magnitudes of the stronger circulation cells. In addition, there is no change in the shape of the circulation cells. This indicates that the volume fraction variation has a slight impact on the flow characteristics of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid. The variation in the volume fraction is more effective in $Fe_3O_4 - MWCNT-$water hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid.

Figure 18 indicates the impact of the volume fraction factor (ϕ) on isotherms for $Fe_3O_4 - MWCNT-$water (Fig. 18-I) and $Fe_3O_4 - MWCNT-$kerosene (Fig. 18-II) hybrid nanofluids. Figures 18 (I-A), 18 (I-B), and 18 (I-C) and 18 (II-A) in order, explain the attributes of isotherms of $Fe_3O_4 - MWCNT-$water hybrid nanofluid with $1\%, 3\%,$ and 5% nanoparticles volume fraction. In case of $Fe_3O_4 - MWCNT-$water hybrid nanofluid, higher heat transmission is noticed in the center of the cavity. More circulating cells are originated at the bottom and top of the cavity whereas few circulation cells are formed near the hot slits and the center of the cavity. There is no significant variation in the shape of the isotherms for increasing the nanoparticle's volume fraction. However, the magnitudes are considerably increased for increasing the nanoparticle's volume fraction. In addition, it is well known that the heat transfer rate is dependent on the concentration (percentage doping) of nanoparticle's volume fraction. As a result, the heat transmission characteristics of the hybrid nanofluids are enhanced extensively with a boost in the nanoparticle volume fraction. Figures 18 (II-A), 18 (II-B) and 18 (II-C) in order elucidate the features of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid with $1\%, 3\%,$ and 5% nanoparticles volume fraction. Increasing the mixture of volume fraction clearly induces modifications in the magnitudes of the isotherms inside the cavity but there is no change in the shape of the isotherms. In $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case, the impact of internal heat generation is very high in the center of the cavity as well as it is expanded in all the directions within the cavity. Most of the heat transfer variations are noticed at the bottom and top sides of the enclosure where the cold slits are considered whereas a single heat transfer variation is observed on the right and left wall sides where the hot slits are considered. It is noticed that greater heat transfer is observed in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case compared to $Fe_3O_4 - MWCNT-$water hybrid nanofluid.

G. Characteristics of Nusselt number distribution

Figure 19 illustrates the local heat transfer rate for various volume fraction values. For enhancing the hybrid nanoparticle's volume fractions, the local Nusselt number profiles are increased. i.e. greater percentage of doping the nanoparticles boosts the heat transferred at the boundaries of the enclosure. More noticeable modifications are observed in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanoliq-

uid case compared to the $Fe_3O_4 - MWCNT-$water hybrid nanoliquid case. The attributes of the average heat transfer rate for different values of volume fraction are demonstrated in Table 5. Apparently, there is a significant variation in the mean heat transfer rate of water and kerosene based nanofluids. The average heat transfer rates of $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids differ by 10.93% when 1% of hybrid nanoparticles are suspended into the base-fluids. The mean heat transfer rate of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is more elevated than $Fe_3O_4 - MWCNT-$water hybrid nanofluid. When 3% of $Fe_3O_4 - MWCNT$ hybrid nanoparticles are suspended into water and kerosene base fluids, the mean heat transfer rate of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is 8.88% higher than that of $Fe_3O_4 - MWCNT-$water hybrid nanofluid. When 5% of $Fe_3O_4 - MWCNT$ nanoparticles are suspended into water and kerosene, the difference in the mean heat transfer rate between $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids is 6.81%.

The impact of the heat sink or source parameters on the local rate of heat transfer is depicted in Fig. 20. Increased heat source parameter values $(Q = +15)$ enrich the local Nusselt number profiles, whereas increasing heat sink parameter values $(Q = -5)$ suppresses the local Nusselt number profiles. $Q = 0$ denotes the non-existence of heat source/sink. In addition, more elevated heat transfer rates are computed in the case of $Fe_3O_4 - MWCNT-$water hybrid nanofluid. Table 6 depicts the mean heat transfer rate characteristics for various heat sink and source parameter values. In the presence of a heat sink, the average heat transfer rate of $Fe_3O_4 - MWCNT-$water hybrid nanofluid is 78.92% lower than that of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid. In the absence of a heat sink/source, the average heat transfer rate of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is 57.62% higher than that of $Fe_3O_4 - MWCNT-$water hybrid nanoliquid. In the presence of a heat source, the average heat transfer rate of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is 6.81% higher than that of $Fe_3O_4 - MWCNT-$water nanofluid. As a result, the increment in the mean heat transfer rate for the investigated nanoliquids varies greatly with changes in heat absorption/generation within the porous cavity. In addition, more elevated heat transfer occurs in the case of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid.

Figure 21 examines the influence of non-Fourier thermal relaxation parameter δ on non-dimensional temperature of both $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids. The Nusselt number is seen to have an inverse relationship with the thermal relaxation parameter. The trends substantiate the Cattaneo-Christov theory that the higher values of (δ_e) physically imply that greater time is needed to transfer heat to particles with low energy when a temperature gradient is present in the medium. The thermal relaxation effect therefore delays heat transmission in nanofluids. It is to be noted that for $(\delta_e = 0)$, the classical Fourier conduction case is retrieved, and in this case, energy transfers without any time lag through the entire medium of the cav-

TABLE V. Variations of hybrid nanofluids' average heat transfer rate with various volume fraction values

Parameter Values	$Fe_3O_4 - MWCNT-$water	$Fe_3O_4 - MWCNT-$kerosene
$\Phi = 0.01$	4.168388139867347	4.624275837501220
$\Phi = 0.03$	4.454226967509394	4.850175712758110
$\Phi = 0.05$	4.760691225892772	5.085262819964906

TABLE VI. Variations of average heat transfer rate with various heat source/sink parameter values

Parameter Values	$Fe_3O_4 - MWCNT-$water	$Fe_3O_4 - MWCNT-$kerosene
$Q = -5$	2.305576754043674	4.125313772987758
$Q = 0$	2.757630803341192	4.346837999491187
$Q = 15$	4.760691225892772	5.085262819964906

ity. From Fig. 21, it is evident that the temperature is higher for the case of Fourier's model ($\delta_e = 0$) than that of the Cattaneo–Christov heat flux model ($\delta_e \neq 0$). The inclusion of the non-Fourier hyperbolic heat conduction model therefore avoids the over-prediction of temperatures associated with the classical Fourier parabolic heat conduction model. In addition, the Cattaneo–Christov heat flux model can represent a material's conducting or non-conducting nature. Further, there is a notable variation in the heat transfer rate estimated with different base fluids (water & kerosene).

V. CONCLUSIONS

The magnetohydrodynamic mixed convective hybrid nanofluid flow inside a square cavity saturated with a porous medium is studied theoretically. The present investigation addresses the relative heat transfer performance of $Fe_3O_4 - MWCNT-$water and $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluids within the cavity. The major conclusions of the present numerical problem are mentioned below:

1. An increase in the Hartmann number diminishes the fluid flow intensity in the middle of the cavity and increases at the top and bottom zones.

2. In the case of the $Fe_3O_4 - MWCNT-$water hybrid nanofluid, increasing values of the Darcy parameter increase the flow at the cavity's center. The magnitudes of the interior circulating cells in the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid case are augmented at the top and bottom of the cavity.

3. Increasing values of Reynolds number increase the energy transmission throughout the cavity in $Fe_3O_4 - MWCNT-$kerosene case. Further noticed that $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid has a higher energy transfer efficiency than $Fe_3O_4 - MWCNT-$water hybrid nanofluid.

4. In forced convection mode, the fluid velocity is greater in the entire cavity for the $Fe_3O_4 - MWCNT-$water hybrid nanofluid compared to $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid.

5. When 5% nanoparticles are suspended into water and kerosene base-fluids, the average heat transfer of $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid is 6.81% higher than $Fe_3O_4 - MWCNT-$water hybrid nanofluid.

6. Compared to the $Fe_3O_4 - MWCNT-$kerosene hybrid nanofluid, the average heat transfer rate of the $Fe_3O_4 - MWCNT-$water hybrid nanofluid is 78.92% lower in the presence of the heat absorption effect.

7. Fourier's model achieves higher temperatures than the Cattaneo–Christov heat flux model.

The current investigation has revealed some luring aspects of mixed, forced, and natural convective electro-magneto-hybrid nanofluid flow and energy transmission within a square porous cavity. $Fe_3O_4 - MWCNT$ hybrid nanoparticles are suspended into two types of conventional fluids. The MAC algorithm (finite difference) is very advanced and uncomplicated for computing the fluid flow problems which may have some relevance to electro conductive hybrid magnetic nano-fuel cells.
